Abstract (en)

[origin: WO2018104024A1] A securing device for securing the wing of a window, door or the like against impermissible opening is designed to detect a state of the wing, which can be in a closed state or in an open state, and to detect a position of a fitting assembly of the wing, which can be moved between an unlocking position and one or more locking positions, wherein the wing can be opened completely, in particular opened by rotation when the fitting assembly is in the unlocking position, and the wing can be opened only to a limited extent, in particular opened by tilting, or is prevented from opening when the fitting assembly is in one of the locking positions. The securing device is also designed to output a state signal, in particular to an alarm device, according to both the detected state of the wing and the detected position of the fitting assembly.
