Abstract (en)

[origin: WO2019018830A1] An optical array formed from unclad fibers that are affixed with a micro-coating of adhesive has been developed to allow for enhanced light collection translating into parallel streams of optical output. The system is designed to be used for applications requiring parallel output streams (e.g. random number generation for parallel computing architectures, observation of position information for optical sensing application, etc.). The system acts as a parallel, pixelated detector for a source where the individual pixels are simultaneously readout.
