Abstract (en)
The present invention relate to a bone conduction mount structure that minimizes rotational components due to vibration of an actuator by adjusting a support position of the actuator by a support mount, in which the actuator and the support mount are used for a bone conduction device. The bone conduction mount structure includes: an actuator disposed in a user's bone direction and generating and transmitting vibration to the bone; and a support mount disposed to surround a portion of an outer side of the actuator, supporting the actuator, and being able to be fixed to a structural member, in which when the actuator is inserted into the support mount by external force, a difference between a center of gravity and a rotational center of the actuator decreases.
