Abstract (en)

[origin: WO2019202012A1] A cover layer (2) is joined to an object (1) by means of a pressing force and mechanical vibration. The cover layer (2) has a cover layer contact surface (28), and the object (1) has an object contact surface (18), and the cover layer contact surface (28) and the object contact surface (18) are placed to face each other. The cover layer (2) or the object (1) or both comprise(s) a joining material. During the process, the cover layer contact surface (28) is brought into contact with the object contact surface (18), and a sonotrode (6) is used to press the cover layer (2) against the object (1) and to apply mechanical vibration to an outer surface of the cover layer (2) for a time sufficient for activating the joining material. Cover layer (2) and object (1) are conveyed relative to the sonotrode (6) in a continuous manner in a conveying direction (CD) throughout the steps of arranging, of bringing into contact, of pressing and of applying vibration. The step of conveying causes a sliding movement, along the conveying direction, of the cover layer relative to a coupling-out (61) face of the sonotrode (6). At least a portion of the coupling-out face (61) is not parallel to the object contact surface so that a distance between the sonotrode and the object contact surface continuously decreases along the coupling-out face portion as function of a position along the conveying direction (CD).
