Abstract (en)

[origin: EP3792640A1] Admittance of an electrical load such as a loudspeaker in an automotive audio system is calculated by:- generating (10) a first voltage signal ($\sin(2\pi f_{in}kT)$) and a second voltage signal ($\cos(2\pi f_{in}kT)$) in quadrature to the first voltage signal,- injecting one ($\sin(2\pi f_{in}kT)$) of these voltage signals into a signal propagation path towards the electrical load,- sensing (CS) a current signal ($i_{in}k$) flowing through the electrical load as a result of the voltage signal ($\sin(2\pi f_{in}kT)$) injected into the signal propagation path towards the electrical load,- processing (101 to 108) the first ($\sin(2\pi f_{in}kT)$) and second ($\cos(2\pi f_{in}kT)$) voltage signals and the current signal ($i_{in}k$) sensed (CS) by executing an approximation procedure (LMS, for instance) of the current signal ($i_{in}k$) sensed (CS) via a linear combination of the first ($\sin(2\pi f_{in}kT)$) and second ($\cos(2\pi f_{in}kT)$) voltage signals via a first (a) and a second (b) linear combination coefficient.The approximation procedure comprises updating (a', a"; b', b") the first (a) and second (b) linear combination coefficients until a target approximation (108) is reached. An admittance of the electrical load is calculated as a function of the updated values of the first (a) and second (b) linear combination coefficients when the target approximation is reached (108).
