Abstract (en)

[origin: WO2019238369A1] The disclosure relates to a protection device (100) for transferring energy from a two-pole voltage terminal (101) to an electrical load (103). A first fuse circuit (105) is designed to interrupt the flow of a line current from the voltage terminal (101) to the electrical load (103) when said line current reaches a first current intensity limit value. An overvoltage protection circuit (107) is designed to short-circuit the voltage terminal (101) when a first voltage limit value is reached, in order to force a line current that reaches the first current intensity limit value and thus to trip the first fuse circuit (105). The overvoltage protection circuit (107) is connected downstream of the first fuse circuit (105) and upstream of the electrical load (103). A second fuse circuit (109) is connected downstream of the overvoltage protection circuit (107) and upstream of the electrical load (103) and is designed to control the overvoltage protection circuit (107) to short-circuit the voltage terminal (101) when the voltage at the second fuse circuit (109) reached a second voltage limit value. The second voltage limit value is defined in dependence on a nominal voltage of the electrical load (103).
