Abstract (en)

A gate driver circuit (2) for driving a gate-controlled switching device (4) comprises a voltage monitor circuit portion (14) arranged to produce a first value that is dependent on a time derivative (dv/dt) of a voltage applied across the gate-controlled switching device (4). A current monitor circuit portion (16) is arranged to produce a second value that is dependent on a time derivative (di/dt) of a current through the gate-controlled switching device (4). A compensator (12) is arranged to receive an alternating input signal (PWM_{ref}), the first value, and the second value, wherein the compensator (12) modulates a magnitude and transition profile of the alternating input signal (PWM_{ref}) in response to the respective time derivatives of the voltage and the current, thereby generating a modulated control signal (PWM_N). The gate driver circuit (2) supplies the modulated control signal (PWM_N) to the gate terminal of the gate-controlled switching device (4).
