Abstract (en)

[origin: EP3855865A1] A terminal device comprises a function capable of operating in a plurality of states that include a first state in which a connection with a base station device has been established, and a second state in which a connection with a base station device has not been established, but the base station device holds information regarding the terminal device. After starting operation in the second state from a state in which the terminal device operates with a first base station device in the first state, if predetermined information that enables communication with the first base station device in the second state and that has been acquired from the first base station device in the first state is held, the terminal device determines whether or not a target to which a signal is to be transmitted has changed from the first base station device to a second base station device, and performs communication according to a result of the determination.
