Abstract (en)

[origin: US2020177517A1] An electronic device (such as an access point or an eNodeB) that selectively provides prioritized communication is described. During operation, the electronic device may receive one or more packets or frames from a second electronic device using a communication protocol. Then, the electronic device may determine device-specific information based at least in part on a device profile associated with the communication protocol and/or a communication history of the second electronic device. Next, based on the determined device-specific information, the electronic device may assign additional data traffic associated with the second electronic device to a queue in a set of queues, where queues in the set of queues have different priorities, and where the queue provides a predefined latency of communication with the second electronic device corresponding to a priority of the queue.
