Abstract (en)

A lever-controllable magnetic buckle includes a male member (20) having a male engaging section (24), a female member (30) having a female engaging section (33) formed with two groups of female guide-out surface (334, 335), and a control lever (60). The male member (20) is magnetically attracted for moving to the female member (30) with the male engaging section (24) retained to the female engaging section (33). The control lever (60) is pivotally connected to the male member (20) and has an actuating cam (61) contacting with the female member (30). The female member (30) will contact with surfaces of the actuating cam (61) at different positions thereof when the control lever (60) is pivotally swung relative to the male member (20), allowing the male engaging section (24) to disengage from the female engaging section (33). Then, the control lever (60) can be further swung to move the male member (20) in different directions to selectively contact with one of the two groups of female guide-out surface (334, 335) and be completely separated from the female member (30).
