Abstract (en)

Embodiments of this application provide a video transmission method, an apparatus, and a system, to reduce generation of redundant data in VR video transmission, reduce a transmission burst bandwidth, and reduce a motion-to-hires latency MTHR. The method includes: A terminal sends first field of view information to a server through a first link based on a first period. Correspondingly, the server receives the first field of view information from the terminal through the first link based on the first period. After determining, based on a second period, that the first field of view information is latest field of view information, the server obtains data of a first frame of image corresponding to the first field of view information, and sends the data of the first frame of image to the terminal through a second link. Correspondingly, the terminal receives the data of the first frame of image from the server through the second link based on the second period.
