Abstract (en)

[origin: WO2022174363A1] A signal processing device (1) processes a receiver signal (20) that has two components which are, or derive from, two polarization components of a received optical signal (23). The receiver signal comprises a plurality of frames (41-45). Each frame comprises a training sequence ("TS") and a payload sequence ("Data"). The payload sequence comprises N sections. A channel state information, CSI, estimator (10) determines CSI of each frame based on the training sequence of the frame. A 2x2 MIMO equalizer equalizes each section of the payload sequence of a current frame based on the CSI of L reference frames among the plurality of frames, wherein the CSI of the L reference frames is weighted. Thus, highly effective equalization is achieved.
