Abstract (en)

Provided is reception apparatus comprising a reception section adapted to receive a physical layer frame transported as a broadcast signal. The monitoring information is included in upper layer signaling that is signaling in a layer higher than a physical layer and is used to monitor a specific emergency warning service. The reception apparatus further comprises a demodulation section adapted to a demodulate physical layer signaling acquired from the physical layer frame and monitor whether emergency warning information has been transported on a basis of emergency warning notice information included in the physical layer signaling. Additionally, the reception apparatus comprises a data processing section adapted to process packets supplied from the demodulation section. The reception section and the demodulation section are adapted to be active in a stand-by mode to monitor the emergency warning notice information while the data processing section is inactive in the stand-by mode. The reception apparatus is adapted to start up the data processing section automatically from the stand-by mode to a normal mode in a case where the emergency warning notice information indicates that the emergency warning information has been transported. The monitoring information includes monitoring target information indicating a uniform resource locator, URL, of an application that is used to acquire an application via a communication line.
