Abstract (en)
[origin: EP4287343A1] Embodiments of the present application provide a method, an apparatus, a device, a medium and a product for detecting alignment of battery electrode plates. The method includes: obtaining depth distances of a target cross section of the battery electrode plates after lamination molding, wherein the target cross section is perpendicular to an electrode plate setting direction of the battery electrode plates, and the depth distances of the target cross section includes the depth distance corresponding to each of the electrode plates; and determining an alignment detection result of the battery electrode plates based on the depth distances of the target cross section. According to embodiments of the present application, the depth distances of the target cross section of the battery electrode plates can be obtained after lamination molding of the battery electrode plates, the depth distances of the target cross section may include the corresponding depth distance of each electrode plate. According to the corresponding depth distance of each electrode plate, the overall alignment of the battery electrode plates after lamination molding can be determined. The battery electrode plates qualified in the detection may be used to perform a subsequent manufacturing process, and the battery electrode plates unqualified in the detection can be treated by waste discharge, so as to ensure the quality of the battery and improve the good product rate of the battery.
