Abstract (en)

[origin: WO2022259183A1] The invention relates to a method for predicting and detecting particular conditions of a horse, in particular for predicting the date of foaling, in which, by means of a processing device, by means of image analysis, the following is determined: the number of breaths of the horse per minute, whether the horse is standing or lying down, a change in the level of activity of the horse. Then the obtained parameter values are analysed using an artificial intelligence model, such as a neural network, and it is determined whether the detected condition of the horse is a particular condition, wherein in case the particular condition is detected, at least one change of the output state of the processing device is made. The invention also relates to a system for predicting and detecting particular conditions of a horse, in particular for predicting the date of foaling, comprising at least one visual camera and a processing device, and wherein the system is configured and programmed to determine the following by means of image analysis: number of breaths of the horse per minute, whether the horse is standing or lying down, a change in the level of activity of the horse. Then the obtained parameter values are analysed using an artificial intelligence model, such as a neural network, and it is determined whether the detected condition of the horse is a particular condition, wherein in case the particular condition is detected, at least one change of the output state of the processing device is made. The invention also relates to a system configured and programmed to carry out the above method.
