## Description

### BACKGROUND OF THE INVENTION

#### Field of the Invention

**[0001]** This invention relates to an engine control system for a hybrid vehicle, and, more particularly, to an engine control system which stops or restarts the engine in consideration of the remaining charge of a high-voltage battery and the amount of power consumption by accessories or other devices.

#### Description of the Related Art

**[0002]** Conventionally, hybrid vehicles which carry motors as power sources for driving the vehicles in addition to engines are known. Hybrid vehicles are divided into series hybrid vehicles and parallel hybrid vehicles. In the series hybrid vehicles, the engine drives a generator whose electric power output is used to drive the motor, which in turn drives the wheels. In the parallel hybrid vehicles, the motor coupled to the engine assists the rotation of the drive shaft of the engine while charging a high-voltage battery with electric energy using the motor itself as a generator or using a separate generator.

**[0003]** Because the engines of such hybrid vehicles can constantly run within the engine-speed range of a high fuel mileage and a low emissions level or their drive loads can be reduced, the hybrid vehicles can achieve lower fuel consumption and lower emissions levels than conventional engine vehicles.

**[0004]** As disclosed in, for example, Japanese Unexamined Patent Application, First Publication Hei 8-317505, some of those hybrid vehicles are designed to be capable of stopping the operation of the engine in accordance with predetermined driving conditions.

**[0005]** Because of the ability to stop the operation of the engine, such a hybrid vehicle is superb in preventing over-charging of the battery or achieving a further improvement on the fuel consumption by stopping the operation of the engine in accordance with predetermined operational conditions, such as the remaining charge of the battery, but has the following problem.

**[0006]** For example, while a certain amount of energy remains in the battery when fuel supply cut is carried out during deceleration, it is not adequate to keep fuel supply cut and stop the engine when the 12-V system consumes a large amount of power and energy should be supplemented from the high-voltage battery to the 12-V battery, e.g., when turning on head lights while driving the vehicle in a night.

**[0007]** US-A-5,212,431 discloses a control system for an electric vehicle, which has an electric motor 17 as driving force source comprising: power storage unit 15 for supplying electric energy to said electric motor and storing energy generated when said electric motor is operated as a generator, a gas turbine type-generator 16

for supplying electric energy to said motor and said generator; and a remaining charge detector for detecting a remaining charge of said power storage unit; a stop/start determination device for determining whether to permit stopping or starting of said generator in accordance with said remaining charge of said power storage unit; a generator stopper for stopping said generator based on a result of a decision by said stop/start determination device; and a generator starter for starting said generator based on said result of said decision by said stop/start determination device.

**[0008]** DE196 20 988 A1 discloses an engine control system for a hybrid vehicle, which has an internal combustion engine 60 and an electric motor 10 as driving force sources, and permits stopping and starting of said engine in accordance with predetermined drive conditions, said engine control system comprising: first power storage unit (high voltage battery) 20 for supplying electric energy to said motor and storing energy generated when said electric motor is operated as a generator by said internal combustion engine and energy regenerated by regeneration; second power storage unit (accessory and engine starter battery) 50 for supplying electric energy to a predetermined accessory device, (e.g. light, radio, airbag, engine starter motor); a voltage detector for detecting voltage of the second power storage unit; start determination device for determining whether to permit starting of said engine in accordance with the detected voltage of the second power voltage unit and the remaining charge of said first power storage unit; and an engine starter for starting said engine based on said result of said decision by said determination device, such that if the voltage of the second power storage unit may soon get low for restarting the engine, the engine is started. There, the voltage of the accessory and starter battery 50 is determined. If the voltage is too low (10 to 12 V) a failure flag F1 is outputted. But only if the DC/DC converter 22 is out of operation over a longer time, and simultaneously, the accessory and starter battery voltage is too low, then the engine is restarted, so that the generator 52 coupled to the engine 16 produces electric power for charging the starter battery 50.

### SUMMARY OF THE INVENTION

**[0009]** Accordingly, it is an object of the present invention to provide an engine control system for a hybrid vehicle, which can stop the engine in accordance with the power consumption of the 12V system.

**[0010]** To achieve this object, according to one aspect of this invention, there is provided an engine control system for a hybrid vehicle, in accordance with claim 1.

**[0011]** The hybrid vehicle is equipped with an internal combustion engine (e.g., an engine E in one embodiment) and an electric motor (e.g., a motor M in the embodiment) as driving force sources and a power storage unit, and permits stopping and starting of the engine in accordance with predetermined drive conditions, com-

prises: power-consumption detector (e.g., the 12V system power-consumption sensor S8 in the embodiment) for detecting the amount of power consumption by a predetermined accessory device (e.g., accessories such as lights and an air conditioner, or an ECU); first power storage unit (e.g., a high-voltage battery BAT in the embodiment) for supplying electric energy to said motor and storing energy generated when the electric motor is operated as a generator by the internal combustion engine and energy regenerated by regeneration; second power storage unit (e.g., a 12-volt (low-voltage) auxiliary battery 12BAT in the embodiment) for supplying electric energy to the predetermined accessory device; remaining charge detector (e.g., a current sensor S<sub>7</sub> or the like in the embodiment) for detecting a remaining charge of the first power storage unit (e.g., a remaining charge QBAT in the embodiment); stop/start determination device (e.g., step S111, step S216 and step S316 in the embodiment) for determining whether to permit stopping or starting of the engine in accordance with the amount of power consumption by the predetermined accessory device (e.g., the amount of 12V system power-consumption VELIDL<sub>n</sub> in the embodiment) and the remaining charge of the power storage unit; engine stopper (e.g., step S129 and step S320 in the embodiment) for stopping the engine based on a result of a decision by the stop/start determination device; and engine starter (e.g., step S209 and step S323 in the embodiment) for starting the engine based on the result of the decision by the stop/start determination device.

**[0012]** With the above structure, because stopping and starting of the engine can be permitted in accordance with the power consumed by the predetermined accessory device and the remaining charge of the first power storage unit, the engine can be stopped according to the actual conditions based not only on the remaining charge of the first power storage unit but also on the amount of power consumption of the predetermined accessory device. This can prevent the occurrence of the situation that while the engine is stopped because of certain amount of charge remains in the power storage unit, a large amount of power consumption by the predetermined accessory device actually reduces the remaining charge of the first power storage and thus disables restarting of the engine.

**[0013]** The predetermined drive conditions for stopping the engine are, for example, such that on the premise that the engine can be started by the motor (e.g., when a motor-start enable/disable flag F\_MOTSTB is "1" in step S106 in the embodiment), the amount of the remaining battery charge (or the state of charge) SOC is equal to or above an over-discharge area (e.g., an energy-storage-zone flag F\_ESZONE is "0" in step S107 in the embodiment), and the engine coolant temperature TW is equal to or higher than a predetermined level (e.g., the coolant temperature TW is equal to or higher than a coolant-temperature lower limit TWFCMG in step S108 in the embodiment).

**[0014]** Preferably, the first power storage unit supplies electric energy to the second power storage unit via a downverter, and is capable of supplying power to drive the predetermined accessory device via the downverter, the stop/start determination device determines to permit stopping of the engine when the remaining charge of the power storage unit is equal to or greater than an upper threshold value of the remaining charge of the power storage unit (e.g., an engine-stop disable high-voltage battery capacity upper limit QBATIDHN in the embodiment) set in association with the amount of power consumption by the predetermined accessory device, and determines to permit starting of the engine when the remaining charge of the power storage unit is equal to or smaller than a lower threshold value of the remaining charge of the power storage unit (e.g., an engine-stop enable high-voltage battery capacity lower limit QBATIDL<sub>N</sub> in the embodiment) set in association with the amount of power consumption by the predetermined accessory device.

**[0015]** The stopping of the engine operation can include fuel supply cut when the vehicle decelerates. This can permit suppression of fuel consumption when the vehicle is decelerating. In this case, returning from the fuel cutting state or restart of fuel supply is implemented in accordance with the remaining charge of the power storage unit and the amount of power consumption by predetermined accessory device.

## BRIEF DESCRIPTION OF THE DRAWINGS

### [0016]

FIG. 1 is a schematic diagram showing the overall structure of one embodiment of this invention

FIG. 2 is a flowchart showing a routine for determining the operation mode of a motor;

FIG. 3 is a flowchart illustrating a routine for determining whether or not to stop the engine of an MT vehicle;

FIG. 4 is a flowchart illustrating a routine for determining whether or not to restart the MT vehicle; and FIG. 5 is a flowchart showing a routine for a determination of engine stop/engine restart of a CVT vehicle.

FIG. 6 is a flowchart for monitoring the power consumption of a 12-V system.

FIG. 7 is a graph illustrating the relationship between the remaining charge of a battery and the power consumption of the 12V system.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

**[0017]** A preferred embodiment of the present invention will be explained with reference to the accompanying drawings.

**[0018]** FIG. 1 is a schematic diagram showing the over-

all structure of a parallel hybrid vehicle, specifically, a hybrid vehicle having a manual transmission system installed therein (including a vehicle in which a CVT (Continuously Variable Transmission) is installed). Driving forces from both an engine E and a motor M are transmitted via a transmission T, such as an automatic transmission or a manual transmission, to front wheels Wf which are the drive wheels. When the hybrid vehicle decelerates and the driving force is transmitted from the front wheels Wf to the motor M, the motor M acts as a generator to generate so-called regenerative braking force, so that the kinetic energy of the vehicle body is stored as electric energy.

**[0019]** A power drive unit PD performs the driving and regeneration of the motor M in response to control commands from a motor ECU 3. A high-voltage battery BAT for sending and receiving electric energy to and from the motor M is connected to the power drive unit PD. The battery BAT includes a number of modules connected in series, each module having a number of cells connected in series. The hybrid vehicle includes a 12-volt auxiliary battery 12BAT for driving various accessories. The auxiliary battery 12BAT is connected to the battery BAT via a downverter DV. The downverter DV, controlled by an engine ECU 1, reduces the voltage from the battery BAT and charges the auxiliary battery 12BAT.

**[0020]** A battery ECU 2, for example, computes the remaining charge (or the state of charge) SOC of the battery BAT. In FIG. 1, reference numeral "4" denotes a brake vacuum control unit, and the broken-line block 5 is a CVTECU.

**[0021]** The engine ECU 1 controls fuel supply amount controller F1 for controlling the amount of fuel supplied to the engine E, a starter motor ST, an ignition timing, etc. in addition to the motor ECU 3 and the downverter DV.

**[0022]** Therefore, the engine ECU 1 receives SOC information on the battery remaining charge from the battery ECU 2, motor information from the motor ECU 3 and signals from various sensors and various switches. The sensors include a vehicle speed (V) sensor S<sub>1</sub>, a throttle-opening-state (TH) sensor S<sub>2</sub>, engine coolant temperature (TW) sensor S<sub>3</sub>, an engine intake-air temperature (TA) sensor S<sub>4</sub>, an engine speed (NE) sensor S<sub>5</sub> and a brake-vacuum sensor S<sub>6</sub> for detecting the brake-master-power negative pressure. There are also a 12-V system power-consumption sensor S<sub>8</sub> for detecting the amount of power consumption by the accessories and a current sensor S<sub>7</sub> which, together with the battery ECU 2, detects the remaining charge of the battery BAT. Those switches, though not illustrated, include an ignition switch, a reverse switch, a brake switch, a neutral switch and a clutch switch.

**[0023]** Based on the signals from the various sensors and the various switches, the SOC information and the motor information, the engine ECU 1 performs fuel supply cut and starting of the engine.

**[0024]** For a CVT-installed vehicle, N (Neutral), P

(Parking) and R (Reverse) position switches are provided in addition to the neutral switch, reverse switch and clutch switch.

#### 5 [Determination of Motor Operation Mode]

**[0025]** Referring to the flowchart of FIG. 2, the control mode for the motor of this hybrid vehicle will be explained.

**[0026]** In step S1, it is determined whether the vehicle is a manual transmission (MT) vehicle or a CVT vehicle. When it is determined that the vehicle is an MT vehicle, an engine stop determination (for MT vehicle) which will be discussed later is carried out in step S2. Then, a restart determination is performed in step S3 after which the flow proceeds to step S5.

**[0027]** When it is determined in step S1 that the vehicle is a CVT vehicle, an engine stop/engine restart determination (for CVT vehicle) which will be discussed later is performed in step S4. Then, the flow proceeds to step S5.

**[0028]** In step S5, an assist trigger determination is executed to determine whether or not to carry out assist by the motor. There are various assisting methods; for example, the determination can be made based on parameters such as the throttle opening state (e.g., throttle opening degree, or throttle opening amount) and the vehicle speed. Then, it is determined in step S6 whether the throttle is completely closed based on a throttle-completely-closed-state flag F\_THIDLGMG.

**[0029]** When in step S6 the throttle-completely-closed-state flag F\_THIDLGMG is "0", that is, when it is determined that the throttle valve is completely closed, and when it is determined in step S7 that the vehicle speed V is "0", that is, the vehicle is not running, the "idle mode" is selected in step S8, so that the engine E is maintained in an idling state.

**[0030]** When in step S6 the throttle-completely-closed-state flag F\_THIDLGMG is "0", that is, when it is determined that the throttle valve is completely closed, and when it is determined in step S7 that the vehicle speed V is not "0", the "deceleration mode" is selected in step S9 and regenerative braking by the motor M is carried out. Further, the regeneration energy is stored to charge the battery.

**[0031]** When in step S6 the throttle-completely-closed-state flag F\_THIDLGMG is "1", that is, when it is determined that the throttle valve is open, the flow proceeds to step S10. In this step S10, it is determined based on a motor assist flag F\_MAST whether to select the "acceleration mode" or the "cruise mode".

**[0032]** When it is determined in step S5 that the assist by the motor M is required, and when it is determined in step S10 that the motor assist flag F\_MAST is "1", the "acceleration mode" is selected in step S11, and the motor M assists the driving force of the engine E. When it is determined in step S10 that the motor assist flag F\_MAST is "0", the "cruise mode" is selected in step S12, and the motor M is not driven so that the vehicle runs only on the driving force from the engine E. Accordingly,

step S13 provides the output from the motor corresponding to each mode.

**[0033]** The following describes the "engine stop determination (MT)", the "restart determination" and the "engine stop/engine restart determination (CVT)" in the above-described flowchart.

#### [Engine Stop Determination (MT)]

**[0034]** Now, the engine stop determination for an MT vehicle will be discussed. In the engine stop determination, specifically, whether or not to permit the engine to stop is determined according to the running conditions of the engine and the driver's operation, basically on the condition that stopping the engine is permitted only when the start of the engine can be assisted by the motor.

**[0035]** FIG. 3 is a flowchart illustrating a routine for determining whether or not to stop the engine of an MT vehicle. The state of a start-switch-ON start flag F\_MGST is determined in step S101 in this flowchart. When the start-switch-ON start flag F\_MGST is "0", that is, when it is the first running, a restart flag F\_IDLREST for restarting the engine by opening the throttle is set to "0" in step S102. Then, the engine-stop control execution flag F\_FCMG is set to "0" in the next step S103. In the next step S104, "0" is set to a flag F\_FCBRK which indicates that the brake is released while fuel supply cut originated from deceleration is continuing, after which the flow returns.

**[0036]** That is, at the time of first running, the individual flags are initialized by the operation from the ON action of the ignition switch to the ON action of the start switch.

**[0037]** When it is determined in step S101 that the start-switch-ON start flag F\_MGST is "1" or it is not the first running, the state of the engine-stop control execution flag F\_FCMG is checked in step S105. The decision here is made to distinguish the condition for stopping the engine from the condition for restarting the engine after the engine has stopped. When the flag F\_FCMG was already "1", this step is passed and the flow returns to the operation-mode determining routine to execute the restart determination.

**[0038]** When it is determined that the engine-stop control execution flag F\_FCMG is "0", it is then determined in step S106 if the motor start enable flag F\_MOTSTB is "1", that is, if the starting of the engine by the motor is possible. Whether or not the start of the engine can be performed by the motor is checked by signals from the motor ECU 3. When it is determined that the flag F\_MOTSTB is "0", the starting of the engine by the motor is not possible so that the flow goes to step S104. When it is determined that the flag F\_MOTSTB is "1", the flow goes to step S107. Thus, if the starting of the engine by the motor is not possible, therefore, the engine will not be stopped.

**[0039]** In step S107, it is determined if the energy-storage-zone flag F\_ESZONE is "1", that is, the battery's remaining charge SOC is in an over-discharge zone (e.g., 20% or smaller). This prevents the engine from being

stopped when the battery's remaining charge is not much.

**[0040]** When the energy-storage-zone flag F\_ESZONE is "1", that is, when it is determined that the battery's remaining charge SOC is in the over-discharge zone, the flow proceeds to step S104. When it is determined that this flag F\_ESZONE is "0", i.e., that the battery's remaining charge SOC is not in the over-discharge zone, the coolant temperature TW is compared with the coolant-temperature lower limit TWFCMG (e.g., 40°C) for stopping the engine in step S108.

**[0041]** When it is determined that the coolant temperature TW is lower than the coolant-temperature lower limit TWFCMG, the flow goes to step S104. This prevents the engine from being stopped when it is not in a fully warmed-up state. When it is determined that the coolant temperature TW is equal to or higher than the coolant-temperature lower limit TWFCMG, the intake-air temperature TA is compared with an intake-air temperature upper limit TAFCMG (e.g., 40°C) for stopping the engine in step S109.

**[0042]** When it is determined that the intake-air temperature TA is higher than the intake-air temperature upper limit TAFCMG, the flow proceeds to step S104. Accordingly, when the intake-air temperature is high, the engine is not stopped in consideration of the deterioration of the startability and the air conditioning performance that should be secured. When it is determined that the intake-air temperature TA is equal to or lower than the intake-air temperature upper limit TAFCMG for stopping the engine, the flow proceeds to step S110.

**[0043]** In step S110, it is determined whether or not the shift position is the position R (Reverse). When a reverse switch flag F\_RVSSW is "1", that is, when it is determined that the shift position is the position R, the flow proceeds to step S104. This prevents the engine from being stopped when the vehicle starts or stops at a low speed in the reverse mode, thus improving the operability. When it is determined that the shift position is other than the position R, the state of a large-consumption-in-12V-system and restart enable flag F\_FCMGBAT is determined in step S111. The control which determines the value of this flag F\_FCMGBAT will be discussed later.

**[0044]** When it is determined that this flag F\_FCMGBAT is "0", that is, when restarting the engine is not possible due to large consumption in the 12V system, the flow advances to step S104. When it is determined that the flag F\_FCMGBAT is "1", that is, when restarting the engine is possible even with large consumption in the 12V system, the flow advances to step S112.

**[0045]** In step S112, it is determined whether or not the throttle-completely-closed-state flag F\_THIDLGM is "1". When the flag F\_THIDLGM is "1", that is, when it is determined that the throttle is not completely closed, the flow advances to step S104. As a result, the engine is not stopped. When the flag F\_THIDLGM is "0", that is, when it is determined that the throttle is completely closed, the flow advances to step S113.

**[0046]** In step S113, the state of a neutral-switch-OK flag F\_OKNSW is determined, and then the state of a clutch-switch-OK flag F\_OKCLSW is determined in step S114. In the next step S115, the state of a brake-switch-OK flag F\_OKBRKSW is determined.

**[0047]** Those steps S113, S114 and S115 determine if their associated switches are functioning adequately. When the switches are not failing, the respective flags are set to "1". When it is determined that the individual switches are normal, the flow advances to step S116. When each flag value is "0" because the associated switch is abnormal or is not checked as normal, the flow goes to step S104.

**[0048]** In step S116, the vehicle speed V is compared with an engine-stop-at-low-speed determining vehicle speed VIDLST (e.g., 3 km/h). This comparison allows fuel supply cut while the vehicle is running (at and after step S122) and the engine to be stopped when the vehicle is stopped (at and after step S117). This can improve the fuel consumption.

**[0049]** When it is determined in step S116 that the vehicle speed V is lower than the engine-stop-at-low-speed determining vehicle speed VIDLST, the state of the restart flag F\_IDLREST for restarting the engine by opening the throttle is determined in step S117. When the flag F\_IDLREST is "1" or when it is determined that the throttle is opened, the flow returns. Accordingly, when the engine is restarted by turning the ignition switch ON or opening the throttle while the engine is stopped, this flag value becomes "1" and the engine will not be stopped again until the vehicle starts moving.

**[0050]** When it is determined that the restart flag F\_IDLREST is "0", the flow advances to step S118. In this step S118, the state of a neutral keeping flag F\_NDLY is determined. When the neutral keeping flag F\_NDLY is "1", that is, when it is determined that the neutral state is maintained for a predetermined time, the flow goes to step S129. When it is determined that this flag F\_NDLY is "0", the flow goes to step S119 which determines the state of a flag F\_FCMGV for checking if the vehicle speed has exceeded a predetermined vehicle speed after starting of the engine by the starter. The expression "after starting of the engine by the starter" means after restarting (the same is true in the following description).

**[0051]** When it is determined that the flag F\_FCMGV is "0", the flow returns. When it is determined that the flag F\_FCMGV is "1", the flow advances to step S120 to check the state of a flag F\_NGRMG for determining if the gear in use is other than the first gear. When this flag F\_NGRMG is "0", that is, when it is determined that the vehicle has stopped during or after running on the first gear, the engine is not stopped because there may be a mode in which the vehicle starts right after stopping, such as a temporary stop mode. In this case, therefore, the flow returns. When it is determined that this flag F\_NGRMG is "1", the state of a clutch-thrust keeping flag F\_CLON is determined in step S121. When the clutch-thrust keeping flag F\_CLON is "0", the flow returns. When

it is determined that the clutch-thrust keeping flag F\_CLON is "1", the flow advances to step S129 to set the engine-stop control execution flag F\_FCMG to "1" after which the flow returns. This causes the engine to stop when the vehicle is stopped without gear change with the clutch kept thrust at a gear position other than the first gear and reverse gear.

**[0052]** When it is determined in step S116 that the vehicle speed V is equal to or higher than the engine-stop-at-low-speed determining vehicle speed VIDLST, the flag F\_FCMGV for checking if the vehicle speed has exceeded a predetermined vehicle speed after starting of the engine by the starter is set to "1", and the restart flag F\_IDLREST for restarting the engine by opening the throttle is set to "0" in step S122. Then, the flow advances to step S123.

**[0053]** In step S123, the vehicle speed V is compared with a vehicle speed upper limit VFCMGST (e.g., 20 km/h) for maintaining fuel supply cut during deceleration. When it is determined that the vehicle speed V is equal to or higher than the vehicle speed upper limit VFCMGST, the flow advances to step S104. When it is determined that the vehicle speed V is lower than the vehicle speed upper limit VFCMGST, the flow advances to step S124 to determine the state of the neutral keeping flag F\_NDLY.

**[0054]** When it is determined that the neutral keeping flag F\_NDLY is "1", the flow advances to step S129. When it is determined that the neutral keeping flag F\_NDLY is "0", the flow moves to step S125. In step S125, the state of the flag F\_NGRMG is checked to determine if a gear other than the first gear has been used. When this flag F\_NGRMG is "0", the flow returns. When the flag F\_NGRMG is "1", the flow advances to step S126 to determine the state of a flag F\_CLNE indicating that the engine speed NE at the time the clutch is thrust is greater than a predetermined value. The predetermined value here is, for example, 700 rpm.

**[0055]** When the engine speed NE at the time the clutch is thrust is greater than the predetermined value, it is determined that the flag F\_CLNE is "0". In this case, the flow returns. When it is determined that the flag F\_CLNE which indicates the result of the comparison of the engine speed NE at the time of thrusting the clutch with the predetermined value is "1", that is, when the clutch is free at an engine speed lower than the predetermined engine speed NE, fuel supply cut during deceleration is maintained. Then, the state of a flag F\_FCBRK indicating the brake having been released while fuel supply cut in deceleration is kept is determined in step S127.

**[0056]** When it is determined that this flag F\_FCBRK is "1", the flow returns. When it is determined that this flag F\_FCBRK is "0", the state of the brake switch is determined in step S128. When it is determined that the brake switch is "OFF", the flow returns. When it is determined that the brake switch is "ON", the engine-stop control execution flag F\_FCMG is set to "1" in step S129, after which the flow returns.

## [Restart Determination]

**[0057]** FIG. 4 is a flowchart illustrating a routine for determining whether or not to restart the engine of an MT vehicle.

**[0058]** In the first step S201, the state of the engine-stop control execution flag F\_FCMG is checked. Because the restart determination is performed when fuel supply cut by stopping the engine continues, when the engine-stop control execution flag F\_FCMG is "0", this flowchart is passed, a restart-inhibiting delay timer tmFCMG when the remaining charge SOC of the battery goes below the lower limit is set in step S210, and the flow returns.

**[0059]** When the engine-stop control execution flag F\_FCMG is "1", it is determined in step S202 whether the clutch switch is "ON" or "OFF". When in step S202 the clutch switch is "ON", that is, when it is determined that the clutch is free, it is then determined in step S203 if the throttle-completely-closed-state flag F\_THIDLGM is "1."

**[0060]** When in step S203 the throttle-completely-closed-state flag F\_THIDLGM is "1", that is, when it is determined that the throttle is not completely closed, the flow advances to step S206. In step S206, engine restart or returning from the fuel supply cut state is performed by opening the throttle and the restart flag F\_IDLREST is set to "1". Stopping the engine or keeping fuel supply cut is therefore avoided by setting the flag this way.

**[0061]** In step S207, the flag F\_FCMGV for checking if the vehicle speed has exceeded the predetermined vehicle speed after starter-oriented starting, the flag F\_NGRMG for checking if the gear in use is other than the first gear, the clutch-thrust keeping flag F\_CLON and the flag F\_CLNE for checking if the engine speed NE at the time of thrusting the clutch is greater than the predetermined value are set to "0." In step S208, the flag F\_FC-BRK which indicates that the brake has been released during deceleration fuel supply cut is set to "1." In step S209, the engine-stop control execution flag F\_FCMG is set to "0" after which the flow advances to step S210, and then the flow returns. This scheme prevents stopping of the engine, or fuel supply cut from being carried out again in other cases than the case where the gear is set to the neutral position again.

**[0062]** When in step S203 the throttle-completely-closed-state flag F\_THIDLGM is "0", that is, when it is determined that the throttle is completely closed, the flow advances to step S204 to determine if the gear has previously been in the neutral position. When it is determined in step S204 that the previous gear position is the neutral one, it is then determined in step S205 if the transmission is currently in gear. When it is determined that the transmission is currently in gear, the flow advances to step S207 to restart the engine or return from the fuel supply cut state.

**[0063]** When it is determined in step S204 that the transmission has previously been in gear or it is determined in step S205 that the transmission is currently in

neutral, the flow moves to step S214.

**[0064]** When in step S202 the clutch switch is "OFF", that is, it is determined that the clutch is engaged, it is then determined in step S211 if the transmission is currently in neutral. When it is determined in step S211 that the transmission is currently in gear, the flow returns after setting the restart-inhibiting delay timer tmFCMG in step S212. When it is determined in step S211 that the transmission is currently in neutral, it is determined in step S213 if the throttle-completely-closed-state flag F\_THIDLGM is "1".

**[0065]** When it is determined in step S213 that the throttle-completely-closed-state flag F\_THIDLGM is "1", the flow advances to step S206. If it is determined in step S211 that the transmission is in neutral and it is determined in step S213 that the throttle is thrust, restarting the engine or returning from the fuel supply cut state is carried out. When it is determined that the throttle-completely-closed-state flag F\_THIDLGM is not "1" or the throttle is completely closed, the flow goes to step S214.

**[0066]** In step S214, the vehicle speed V is compared with the engine-stop-at-low-speed determining vehicle speed VIDLST. When it is determined that the vehicle speed V is lower than the engine-stop-at-low-speed determining vehicle speed VIDLST, the flow advances to step S216. When it is determined that the vehicle speed V is equal to or higher than the engine-stop-at-low-speed determining vehicle speed VIDLST, it is determined in step S215 if the brake switch is "ON" or "OFF". When in step S215 the brake switch is "OFF", the flow goes to step S208. When the brake is released during fuel supply cut while running, therefore, the engine returns from the fuel supply cut state. When the brake switch is "ON", on the other hand, the flow goes to step S216.

**[0067]** In step S216 is determined the flag F\_FCMG-BAT for determining whether or not to restart the engine based on the reduction in the remaining charge of the battery. When the restart flag F\_FCMGBAT is "0", that is, when it is determined that the engine should be restarted because the battery's remaining charge has dropped, the flow advances to step S217.

**[0068]** When in step S216 the restart flag F\_FCMGBAT is "1", that is, it is determined that restarting of the engine is unnecessary, the restart-inhibiting delay timer tmFCMG is set in step S218, and the flow then goes to step S219.

**[0069]** In step S217, the state of the restart-inhibiting delay timer tmFCMG is checked.

**[0070]** When in step S217 the restart-inhibiting delay timer tmFCMG is "0", the flow advances to step S207. When it is determined that the restart-inhibiting delay timer tmFCMG is not equal to "0", the flow advances to step S219.

**[0071]** In step S219, the absolute value of the brake-master-power negative pressure MPGA is compared with the absolute value of the brake-master-power negative pressure upper limit #MPFCMG (e.g., -430 mmHg). It is desirable that the brake-master-power negative pres-

sure upper limit #MPFCMG be -465 mmHg, for example, when the vehicle is stopped, and be -540 mmHg when the vehicle is running in which state the negative pressure is easily secured.

**[0072]** When it is determined in this step that the brake-master-power negative pressure MPGA is equal to or lower than the brake-master-power negative pressure upper limit #MPFCMG ("YES"), a sufficient negative pressure is secured so that the flow returns without re-starting the engine.

**[0073]** When it is determined that the brake-master-power negative pressure MPGA is closer to the atmospheric pressure than the brake-master-power negative pressure upper limit #MPFCMG ("NO"), the flow advances to step S208 to restart the engine.

**[0074]** In the case that the negative pressure of the brake-master-power is likely to be gone due to pumping of the brake applied during stopping of the engine or the fuel supply cut process, the engine is restarted or the engine returns from the fuel supply cut state in order to secure the brake force, so that the brake-master-power negative pressure MPGA is secured.

#### [Engine Stop/Engine Restart Determination]

**[0075]** The following describes the engine stop/engine restart determination for a CVT vehicle. FIG. 5 is a flow-chart showing a routine for the determination of engine stop of a CVT vehicle.

**[0076]** In step S301 in this figure, the state of the start-switch-ON start flag F\_MGST is checked. When the start-switch-ON start flag F\_MGST is "0", that is, when it is determined that it is the first running, a timer tmSFTR for waiting for stabilization of a change in shift range is set in step S302. In step S322, both the flag F\_FCMGV for checking if the vehicle speed has exceeded a predetermined vehicle speed after starting of the engine by the starter and an engine-stop request flag F\_FCMGSTB for the CVT are set to "0". Then, the engine-stop control execution flag F\_FCMG is set to "0" in step S323 and the flow returns.

**[0077]** When in step S301 the start-switch-ON start flag F\_MGST is "1", that is, when it is determined that it is not the first running, it is determined in step S303 whether or not communication information P\_MOTSTB from the motor ECU 3 is "1". This communication information P\_MOTSTB indicates that the motor-assisted starting of the engine is possible when it is "1", and indicates the motor-assisted starting of the engine is not possible when it is "0".

**[0078]** When in step S303 the communication information P\_MOTSTB is "1", the coolant temperature TW is compared with the coolant-temperature lower limit TWFCMG below which the engine is to be stopped in the next step S304.

**[0079]** When it is determined that the coolant temperature TW is lower than the coolant-temperature lower limit TWFCMG, the flow advances to step S302. This

prevents the engine from being stopped when the engine is not fully warmed up. When it is determined that the coolant temperature TW is equal to or higher than the coolant-temperature lower limit TWFCMG, the intake-air temperature TA is compared with the intake-air temperature upper limit TAFCMG above which the engine is to be stopped in step S305.

**[0080]** When it is determined that the intake-air temperature TA is higher the intake-air temperature upper limit TAFCMG, the flow advances to step S302. As a result, the engine is not stopped in consideration of the deterioration of the startability and the air conditioning performance that should be secured. When it is determined that the intake-air temperature TA is equal to or lower than the intake-air temperature upper limit TAFCMG, the flow proceeds to step S306.

**[0081]** In the next step S306, the state of the brake-switch-OK flag F\_OKBRKSW is checked. This step checks if the brake switch is functioning properly, and a flag value of "1" is set when the switch is not failing. When it is determined that the brake switch is normal, the flow advances to step S307. When the brake switch is abnormal and the flag value is "0", the flow goes to step S302.

**[0082]** In step S307, it is determined if the shift position is in the N (Neutral) range, P (Parking) range or in another range.

**[0083]** When it is determined that the shift position is in a range other than the N range and P range, the state of a drive-range flag F\_CVTEDX is determined in step S308. This drive-range flag F\_CVTEDX indicates the D range when the decision value is "0" and indicates the R range or other ranges when the decision value is "1."

**[0084]** When in step S308 the drive-range flag F\_CVTEDX is "1", the flow goes to step S310 to stop the engine. When the drive-range flag F\_CVTEDX is "0", on the other hand, it is determined in step S309 if the shift-range stabilization waiting timer tmSFTR is "0". When in S309 the shift-range stabilization waiting timer tmSFTR is "0", the flow advances to step S322. When the shift-range stabilization waiting timer tmSFTR is not "0", the flow returns.

**[0085]** As the shift-range stabilization waiting timer tmSFTR is provided, even when the shift position passes the R range at the time the gear is shifted between the D range and the P range, the number of times of the engine is stopped by releasing the stopping of the engine is not reduced.

**[0086]** When it is determined in step S307 that the shift range is in the N range or the P range, the shift-range stabilization waiting timer tmSFTR is set in the next step S310 to stop the engine.

**[0087]** In the subsequent step S311 is checked the state of the flag F\_FCMGV for checking if the vehicle speed has exceeded a predetermined vehicle speed after starting of the engine by the starter.

**[0088]** When it is determined that the flag F\_FCMGV is "0", the flow advances to step S312 where vehicle speed V is compared with an engine-stop-at-low-speed determining vehicle speed VIDLSTC (e.g., 15 km/h).

**[0089]** When it is determined in step S312 that the vehicle speed V is lower than the engine-stop-at-low-speed determining vehicle speed VIDLSTC, the flow advances to step S322. When it is determined that the vehicle speed V is equal to or higher than the engine-stop-at-low-speed determining vehicle speed VIDLSTC, the flag F\_FCMGV is set to "1" in step S313.

**[0090]** Those steps S311, S312 and S313 do not set the flags, that have been initialized (step S322) by restarting after the engine was stopped, to "1" until the vehicle speed V exceeds the engine-stop-at-low-speed determining vehicle speed VIDLSTC.

**[0091]** In a case of heavy traffic, temporary stopping and restarting or the like, stopping and restarting are likely to be frequently repeated. As in step S119 for an MT vehicle, therefore, once the engine is restarted, it will not be stopped again until it runs for a certain distance.

**[0092]** In step S321, the state of the brake switch is determined. When it is determined that the brake switch is "ON", the flow advances to step S315 to check the state of the throttle-completely-closed-state flag F\_THIDLGM. When the throttle-completely-closed-state flag F\_THIDLGM is "1", that is, when it is determined that the throttle is not completely closed, the flow goes to step S322. As a result, the engine is not stopped. When the throttle-completely-closed-state flag F\_THIDLGM is "0", that is, when it is determined that the throttle is completely closed, the flow goes to step S316 to check the state of the flag F\_FCMGBAT for determining whether or not to restart the engine based on the reduction in the remaining charge of the battery ,

**[0093]** When this flag F\_FCMGBAT is "0", that is, when it is necessary to restart the engine as a result of the battery's remaining charge having fallen, the flow goes to step S322. When the flag F\_FCMGBAT is "1", that is, when restarting the engine originating from the reduction in the battery's remaining charge is unnecessary, the flow goes to step S317.

**[0094]** In step S317, the absolute value of the brake-master-power negative pressure MPGA is compared with the absolute value of the brake-master-power negative pressure upper limit #MPFCMG for determining whether to stop the engine.

**[0095]** When it is determined in this step that the brake-master-power negative pressure MPGA is equal to or lower than the brake-master-power negative pressure upper limit #MPFCMG ("YES"), the flow advances to step S318 to stop the engine.

**[0096]** When it is determined that the brake-master-power negative pressure MPGA is closer to the atmospheric pressure than the brake-master-power negative pressure upper limit #MPFCMG ("NO"), the flow goes to step S322 to restart the engine.

**[0097]** In the case that the negative pressure of the brake-master-power negative pressure is likely to be gone due to pumping of the brake applied during stopping of the engine or the fuel supply cut process, the engine is restarted or the engine returns from the fuel supply cut

state in order to secure the brake force, so that the brake-master-power negative pressure MPGA is secured. This can relieve the burden that would otherwise be put on the driver due to an insufficient brake-master-power negative pressure MPGA.

**[0098]** Then, the engine-stop request flag F\_FCMGSTB is set to "1" in step S318, and the state of a CVT-engine stop-OK flag F\_CVTOK is checked in step S319. When the CVT-engine stop-OK flag F\_CVTOK is "1", that is, when it is determined that the engine is ready to be stopped, the engine-stop control execution flag F\_FCMG is set to "1", and then the flow returns. When the CVT-engine stop-OK flag F\_CVTOK is "0", that is, when it is determined that the engine is not ready to be stopped, the engine-stop control execution flag F\_FCMG is set to "0", after which the flow returns.

**[0099]** In the step S321, the state of the brake switch is checked. When it is determined that the brake switch is "OFF", both the flag F\_FCMGV for checking if the vehicle speed has exceeded a predetermined vehicle speed after starting of the engine by the starter, and the engine-stop request flag F\_FCMGSTB to the CVT are set to "0". Then, the engine-stop control execution flag F\_FCMG is set to "0", after which the flow returns.

[Monitoring Power Consumption by 12-V System]

**[0100]** Referring now to FIGS. 6 and 7, a description will be given of the control that determines the value of the large-consumption-in-12-V-system and restart enable flag F\_FCMGBAT in step S111 in the engine stop determining routine (MT), in step S216 in the restart determining routine and in step S316 in the engine stop determining routine (CVT). It is to be noted that the power consumption of the 12-V system is power that is consumed by accessories such as head lamps. The power is supplied from the 12-V battery 12BAT. When the remaining charge of the 12-V battery 12BAT decreases, the power that is lost is supplied to the 12V battery 12BAT via the downverter DV from the high-voltage battery BAT.

**[0101]** In step S401 in FIG. 6, the state of a high-voltage battery remaining-charge-based engine stop lower limit flag F\_FCBATL is checked. When the battery's remaining charge is less than a predetermined value to be discussed later, this flag F\_FCBATL is set to "1", whereas when the vehicle speed V is equal to or higher than the engine-stop-at-low-speed determining vehicle speed VIDLST (e.g., 5 km/h), the flag F\_FCBATL is set to "0."

**[0102]** When it is determined in step S401 that the state of the flag F\_FCBATL is "1", the vehicle speed V is compared with the engine-stop-at-low-speed determining vehicle speed VIDLST. When it is determined that the vehicle speed V is lower than the vehicle speed VIDLST, "0" is set to the large-consumption-in-12V-system and restart enable flag F\_FCMGBAT in step S412, inhibiting the stopping of the engine (step S209 and step S323). That is, when the remaining charge of the high-voltage battery BAT is low and the vehicle speed is low, the re-

maining charge of the battery BAT cannot become unrecoverable so that stopping the engine is inhibited.

**[0103]** When it is determined in step S402 that the vehicle speed V is lower than the vehicle speed VIDLST, the high-voltage battery remaining-charge-based engine stop lower limit flag F\_FCBATL is set to "0" in step S403 after which the flow then proceeds to step S404. When this flag F\_FCBATL is "1" in step S401, the flow also proceeds to step S404.

**[0104]** In step S404, the state of the engine-stop control flag F\_FCMG is determined. When it is determined that the flag F\_FCMG is "1", the flow goes to step S405. When it is determined that the flag F\_FCMG is "0", on the other hand, the flow goes to step S409.

**[0105]** In step S405, the state of the flag F\_FCMGBAT is determined. When the determined value is "1", the flow goes to step S406, whereas when the determined value is "0", the flow goes to step S409.

**[0106]** That is, when idling is not stopped ("NO" in step S404) and when stopping the engine is not permitted by the flag F\_FCMGBAT while idling is stopped ("0" in step S405), an engine-stop disable high-voltage battery capacity upper limit QBATIDHN table is searched based on 12-V system average power-consumption VELAVE in step S409 as shown in FIG. 7.

**[0107]** When idling is stopped ("YES" in step S404) and when stopping the engine is permitted by the flag F\_FCMGBAT ("1" in step S405), an engine-stop enable high-voltage battery capacity lower limit QBATIDLN table is searched based on the 12V system average power-consumption VELAVE in step S406 as shown in FIG. 7.

**[0108]** The QBATIDHN table is searched in step S409, and the battery's remaining charge QBAT (the same as the battery's remaining charge SOC) is compared with the engine-stop disable high-voltage battery capacity upper limit QBATIDHN in step S410. That is, this discrimination is made to check whether or not the engine can be stopped.

**[0109]** When it is determined in this step S410 that the battery's remaining charge QBAT is equal to or greater than the upper limit QBATIDHN, the large-consumption-in-12V-system and restart enable flag F\_FCMGBAT is set to "1" in step S411, thus permitting the engine to be stopped, and then the flow returns.

**[0110]** The QBATIDLN table is searched in step S406, and the battery's remaining charge QBAT is compared with the engine-stop enable high-voltage battery capacity lower limit QBATIDLN in step S407. That is, this discrimination is made to check whether or not the engine can be started (or stopping the engine can be permitted).

**[0111]** When it is determined in this step S407 that the battery's remaining charge QBAT is equal to or greater than the lower limit QBATIDLN, the flow returns. When it is determined that the battery's remaining charge QBAT is smaller than the lower limit QBATIDLN, on the other hand, the high-voltage battery remaining-charge-based engine stop lower limit flag F\_FCBATL is set to "1" and the flow proceeds to step S412. In step S412, the large-

consumption-in-12V-system and restart enable flag F\_FCMGBAT is set to "0", thus inhibiting the stopping of the engine. Then, the flow returns to the operation-mode determining routine.

**[0112]** In FIG. 7, the horizontal scale represents the amount of power consumption (e.g., the average value) VELIDLn (ampere) of the 12V system (accessories), and the vertical scale the battery's remaining charge QBAT. The starting point of the engine-stop disable high-voltage battery capacity upper limit QBATIDHN is 25.4% and the starting point of the engine-stop enable high-voltage battery capacity lower limit QBATIDLN is 25%. It is to be noted that the battery's remaining charge QBAT of 25% is the lower limit at which the engine can be restarted.

**[0113]** The line of the upper limit QBATIDHN gradually moves away from the line of the lower limit QBATIDLN so as to set the time constant between the line of the upper limit QBATIDHN that indicates the lower limit of the engine-stop enable range to the line of the lower limit QBATIDLN that indicates the upper limit below which restarting the engine is needed, for example, when the battery's remaining charge decreases with constant power consumption of the 12V system. This prevents the engine-stop sustaining period from varying depending on the amount of the power consumption of the 12V system, and thus eliminates the situation wherein with a large amount of the power consumed by the 12V system, the engine should be restarted immediately after it is stopped, which would make the driver feel uncomfortable.

**[0114]** Even when a certain amount of the remaining charge of the battery is secured in step S107, for example, the engine stop control can be executed in consideration of the power consumption of the accessories by checking the state of the large-consumption-in-12V-system and restart enable flag F\_FCMGBAT or checking if it is the engine-stop enable state or the engine-restart enable state in consideration of the power consumption of the 12V system in step S111.

**[0115]** This invention is not limited to the above-described embodiment; although the foregoing description has been given of the case where the operation voltage of accessories is 12 V, it may be set to other voltages than 12 V.

**[0116]** According to this invention, as described above, because stopping and starting of the engine can be permitted in accordance with the consumed power of accessories as well as the remaining charge of the power storage unit, it is possible to prevent the occurrence of such an even that while the engine is stopped because of a certain amount of charges remaining in the power storage unit, a large amount of power consumption by the accessories actually reduces the remaining charge of the power storage and thus disables the restarting of the engine.

**[0117]** Further, this invention has such the advantage of making it possible to determine whether or not stopping the engine should be permitted and restarting the engine

should be permitted in accordance with the amount of power consumption by the accessories.

**[0118]** The engine control system, according to the present invention, for a hybrid vehicle, which has an internal combustion engine and an electric motor as driving force sources, and permits stopping and starting of the engine in accordance with predetermined drive conditions, the engine control system comprises: power-consumption detector for detecting an amount of power consumption by predetermined device; first power storage unit for supplying electric energy to the motor and storing energy generated when the electric motor is operated as a generator by the internal combustion engine and energy regenerated by regeneration; second power storage unit for supplying electric energy to the predetermined device; remaining-amount detector for detecting a remaining charge of said first power storage unit; stop/start determination device for determining whether to permit stopping or starting of the engine in accordance with the amount of power consumption by the predetermined device and the remaining charge of the first power storage unit; engine stopper for stopping the engine based on a result of a decision by the stop/start determination device; and engine starter for starting the engine based on the result of the decision by the stop/start determination device.

## Claims

1. An engine control system for a hybrid vehicle, which has an internal combustion engine (E) and an electric motor (M) as driving force sources, and permits stopping and starting of said engine in accordance with predetermined drive conditions, said engine control system comprising:

power-consumption detector (S8) adapted to detect an amount of power consumption by a predetermined accessory device;  
 first power storage unit (BAT) adapted to supply electric energy to said electric motor (M) and storing energy generated when said electric motor (M) is operated as a generator by said internal combustion engine (E) and energy regenerated by regeneration;  
 second power storage unit (12BAT) adapted to supply electric energy to said predetermined accessory device;  
 remaining charge detector (S7) adapted to detect a remaining charge (QBAT) of said first power storage unit (BAT);  
 stop/start determination device (S111, S216, S316) adapted to determine whether to permit stopping or starting of said engine (E) in accordance with said amount of power consumption (VELIDLu) by said predetermined accessory device and said remaining charge (QBAT) of said

first power storage unit (BAT);

engine stopper (S129, S320) adapted to stop said engine (E) based on a result of a decision by said stop/start determination device (S111, S216, S316); and

engine starter (S209, S323) adapted to start said engine (E) based on said result of said decision by said stop/start determination device (S111, S216, S316).

2. An engine control system according to claim 1, wherein said first power storage unit (BAT) is adapted to supply electric energy to said second power storage unit (12BAT) via a downverter (DV), and is capable of supplying power to drive said predetermined accessory device via said downverter (DV), said stop/start determination device (S111, S216, S316) is adapted to determine to permit stopping of said engine (E) when said remaining charge of said power storage unit (BAT) is equal to or greater than an upper threshold value (QBATIDHN) of said remaining charge of said power storage unit (BAT) set in association with said amount of power consumption (VELIDLu) by said predetermined accessory device, and to determine to permit starting of said engine (E) when said remaining charge (QBAT) of said power storage unit (BAT) is equal to or smaller than a lower threshold value (QBATIDLN) of said remaining charge of said power storage unit (BAT) set in association with said amount of power consumption (VELIDLu) by said predetermined accessory device.

## Patentansprüche

1. Maschinenregelungssystem für ein Hybridfahrzeug, welches eine Brennkraftmaschine (E) und einen Elektromotor (M) als Antriebskraftquellen aufweist und das Stoppen und Starten der Maschine gemäß vorbestimmten Fahrzuständen gestattet, wobei das Maschinenregelungssystem umfasst:

einen Stromverbrauchsdetektor (S8), der dazu ausgelegt ist, einen Stromverbrauchsbetrag von einer vorbestimmten Zusatzvorrichtung zu erfassen;  
 eine erste Stromspeichereinheit (BAT), die dazu ausgelegt ist, dem Elektromotor (M) elektrische Energie zuzuführen und Energie, die erzeugt wird, wenn der Elektromotor (M) von der Brennkraftmaschine (E) als Generator betrieben wird, sowie Energie, die durch Regeneration regeneriert wird, zu speichern;  
 eine zweite Stromspeichereinheit (12BAT), die dazu ausgelegt ist, der vorbestimmten Zusatzvorrichtung elektrische Energie zuzuführen;  
 einen Restladungsdetektor (S7), der dazu ausgelegt ist, eine Restladung (QBAT) der ersten

- Stromspeichereinheit (BAT) zu erfassen;  
 eine Stopp/Start-Bestimmungsvorrichtung  
 (S111, S216, S316), die dazu ausgelegt ist, ge-  
 mäß dem Stromverbrauchsbetrag (VELIDLu) 5  
 durch die vorbestimmte Zusatzvorrichtung und  
 der Restladung (QBAT) der ersten Stromspei-  
 chereinheit (BAT) zu bestimmen, ob ein Stop-  
 pen oder Starten der Maschine (E) gestattet  
 wird;  
 einen Maschinenstopper (S129, S320), der da- 10  
 zu ausgelegt ist, die Maschine (E) basierend auf  
 einem Ergebnis der Entscheidung durch die  
 Stopp/Start-Bestimmungsvorrichtung (S111,  
 S216, S316) zu stoppen; und  
 einen Maschinenstarter (S209, S323), der dazu 15  
 ausgelegt ist, die Maschine (E) basierend auf  
 dem Ergebnis der Entscheidung durch die  
 Stopp/Start-Bestimmungsvorrichtung (S111,  
 S216, S316) zu starten. 20
2. Maschinenregelungssystem nach Anspruch 1, wor-  
 in die erste Stromspeichereinheit (BAT) dazu aus-  
 gelegt ist, der zweiten Stromspeichereinheit  
 (12BAT) über einen Niederwandler (DV) elektrische  
 Energie zuzuführen, und in der Lage ist, Strom zum 25  
 Antrieb der vorbestimmten Zusatzvorrichtung über  
 den Niederwandler (DV) zuzuführen, wobei die  
 Stopp/Start-Bestimmungsvorrichtung (S111, S216,  
 S316) dazu ausgelegt ist, zu bestimmen, das Stop-  
 pen der Maschine (E) zu gestatten, wenn die Rest- 30  
 ladung der Stromspeichereinheit (BAT) gleich oder  
 größer als ein oberer Schwellenwert (QBATIDHN)  
 der Restladung der Stromspeichereinheit (BAT) ist,  
 der in Zuordnung zu dem Stromverbrauchsbetrag  
 (VELIDLu) durch die vorbestimmte Zusatzvorrich- 35  
 tung gesetzt wird, und zu bestimmen, das Starten  
 der Maschine (E) zu gestatten, wenn die Restladung  
 (QBAT) der Stromspeichereinheit (BAT) gleich oder  
 kleiner als ein unterer Schwellenwert (QBATIDLN)  
 der Restladung der Stromspeichereinheit (BAT) ist, 40  
 der in Zuordnung zu dem Stromverbrauchsbetrag  
 (VELIDLu) durch die vorbestimmte Zusatzvorrich-  
 tung gesetzt ist. 45

## Revendications

1. Système de commande de moteur à combustion  
 pour un véhicule hybride, qui comporte un moteur à  
 combustion interne (E) et un moteur électrique (M) 50  
 comme sources de force d'entraînement, et permet  
 l'arrêt et le démarrage dudit moteur à combustion en  
 conformité avec des conditions de conduite prédé-  
 terminées, ledit système de commande de moteur  
 à combustion comprenant : 55
- un détecteur de consommation d'énergie (S8)  
 adapté pour détecter une quantité de consom-

mation d'énergie par un dispositif accessoire  
 prédéterminé ;  
 une première unité de stockage d'énergie (BAT)  
 adaptée pour fournir de l'énergie électrique  
 audit moteur électrique (M) et stocker de l'éner-  
 gie générée lorsque ledit moteur électrique (M)  
 est mis en oeuvre comme générateur par ledit  
 moteur à combustion interne (E) et l'énergie ré-  
 générée par régénération ;  
 une seconde unité de stockage d'énergie  
 (12BAT) adaptée pour fournir de l'énergie élec-  
 trique audit dispositif accessoire prédéterminé ;  
 un détecteur de charge restante (S7) adapté  
 pour détecter une charge restante (QBAT) de  
 ladite première unité de stockage d'énergie  
 (BAT) ;  
 un dispositif de détermination d'arrêt/de démar-  
 rage (S111, S216, S316) adapté pour détermi-  
 ner s'il faut permettre l'arrêt ou le démarrage  
 dudit moteur à combustion (E) en conformité  
 avec ladite quantité de consommation d'énergie  
 (VELIDLu) par ledit dispositif accessoire prédé-  
 terminé et ladite charge restante (QBAT) de la-  
 dite première unité de stockage d'énergie  
 (BAT) ;  
 un arrêt de moteur à combustion (S129, S320)  
 adapté pour arrêter ledit moteur à combustion  
 (E) d'après un résultat d'une décision par ledit  
 dispositif de détermination d'arrêt/de démarra-  
 ge (S111, S216, S316) ; et  
 un démarreur de moteur à combustion (S209,  
 S323) adapté pour démarrer ledit moteur à com-  
 bustion (E) d'après ledit résultat de ladite déci-  
 sion par ledit dispositif de détermination d'ar-  
 rêt/de démarrage (S111, S216, S316).

2. Système de commande de moteur à combustion se-  
 lon la revendication 1, dans lequel ladite première  
 unité de stockage d'énergie (BAT) est adaptée pour  
 fournir de l'énergie électrique à ladite seconde unité  
 de stockage d'énergie (12BAT) via un convertisseur  
 abaisseur (DV), et est capable de fournir l'énergie  
 pour entraîner ledit dispositif accessoire prédétermi-  
 né via ledit convertisseur abaisseur (DV), ledit dis-  
 positif de détermination d'arrêt/de démarrage (S111,  
 S216, S316) est adapté pour déterminer de permet-  
 tre l'arrêt dudit moteur à combustion (E) lorsque la-  
 dite charge restante de ladite unité de stockage  
 d'énergie (BAT) est supérieure ou égale à une valeur  
 seuil supérieure (QBATIDHN) de ladite charge res-  
 tante de ladite unité de stockage d'énergie (BAT)  
 fixée en association avec ladite quantité de consom-  
 mation d'énergie (VELIDLu) par ledit dispositif ac-  
 cessoire prédéterminé, et pour déterminer de per-  
 mettre le démarrage dudit moteur à combustion (E)  
 lorsque ladite charge restante (QBAT) de ladite unité  
 de stockage d'énergie (BAT) est inférieure ou égale  
 à une valeur seuil inférieure (QBATIDLN) de ladite

charge restante de ladite unité de stockage d'énergie (BAT) fixée en association avec ladite quantité de consommation d'énergie (VELIDLu) par ledit dispositif accessoire prédéterminé.
