(54) Method of measuring reception timing of a frequency correction burst

(57) A method of detecting an FCB for communication with a base station in a wireless terminal of a wireless communication terminal is provided. The wireless terminal receives a plurality of data blocks including a predetermined FCB, each having a plurality of data symbols, and determines a data block estimated to have the end of the FCB among the data blocks. The wireless terminal determines as the end of the FCB a symbol previous to the first of symbols having energy values less than a predetermined threshold among the symbols of the determined data block.

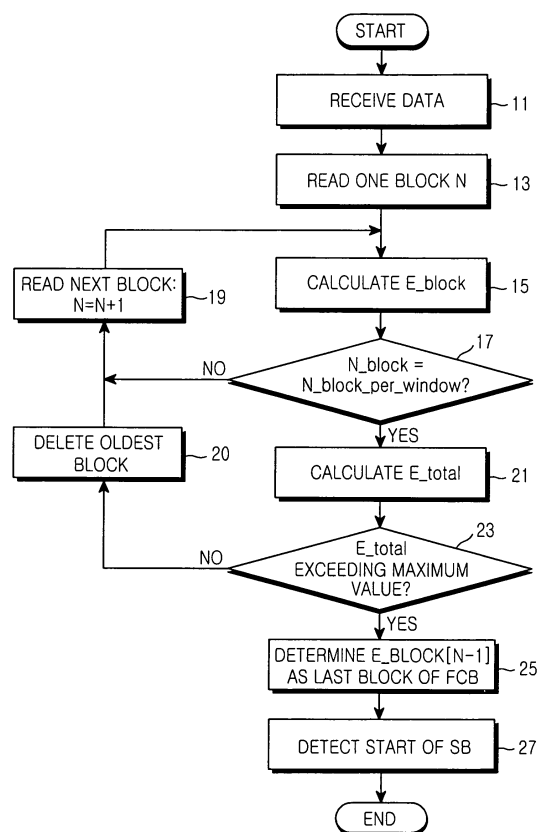

FIG.2

Description**BACKGROUND OF THE INVENTION****1. Field of the Invention**

[0001] The present invention relates generally to data reception in a GSM/GPRS (Global System for Mobile Telecommunication/General packet Radio Service) terminal, and in particular, to a method for improving a timing resolution in detecting an FCB (Frequency Correction Burst).

2. Description of the Related Art

[0002] In GSM/GPRS, only one user receives data from a base station in one time slot in a TDMA (Time Division Multiple Access) scheme.

[0003] A signal from the base station is a so-called burst. There are FCB, SB (Synchronization Burst), and NB (Normal Burst).

[0004] The FCB is used for coarse synchronization between a mobile terminal and a base station. The SB provides system information and more accurate synchronization information to the mobile terminal. NB delivers data between the base station and the mobile terminal. When it is to access a new base station, the mobile terminal acquires synchronization to the new base station by sequentially detecting the FCB and the SB. The base station transmits the FCB at a period of 11 or 12 frames. Thus, if the mobile terminal fails to detect the FCB, it waits a long time to receive the next FCB.

[0005] FIGS. 1A, 1B and 1C illustrate the structures of the FCB, SB and NB. Referring to FIGs. 1A, 1B and 1C, the FCB is made up of a pair of 3-bit tails, a 142-bit synchronization sequence being all zeroes, and an 8.25-bit guard period. The SB includes a pair of 3-bit tails, a pair of 39-bit data areas, and a 64-bit synchronization sequence. The NB is made up of a pair of 1-bit string flags (S), a pair of 64-bit coded data areas, and a 26-bit training sequence.

[0006] Because the FCB is all zeroes, the baseband FCB after a predetermined modulation is a sine wave of 67.7kHz lasting for one burst period. Thus, the mobile terminal detects the 67.7-kHz sine wave by calculating the energy of the 142 bits, while shifting a starting point block by block. With respect to the start of the sine wave, the mobile terminal predicts the start of an SB in the next frame.

[0007] The energy calculation is carried out by shifting a 142-bit window bit by bit. That is, after calculating the energy of one window, one new symbol is added to the window and the oldest symbol is deleted from the window. Then, the energy of the new window is calculated. In this manner, the start or end of the burst is accurately detected. However, a distinctive shortcoming of this method is a large volume of computation because as many calculations as the number of symbols in the burst are required.

[0008] The resulting increase of implementation complexity increases, in turn, hardware and software complexity and lengthens processing time.

SUMMARY OF THE INVENTION

[0009] An object of the present invention is to substantially solve at least the above problems and/or disadvantages and to provide at least the advantages below. Accordingly, an object of the present invention is to provide a method of minimizing a timing error in FCB detection and reducing waste of resources involved in SB reception.

[0010] The above object is achieved by providing a method of detecting an FCB for communication with a base station in a wireless terminal of a wireless communication terminal is provided. The wireless terminal receives a plurality of data blocks including a predetermined FCB, each having a plurality of data symbols, and determines a data block estimated to have the end of the FCB among the data blocks. The wireless terminal determines as the end of the FCB a symbol previous to the first of symbols having energy values less than a predetermined threshold among the symbols of the determined data block.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] The above and other objects, features and advantages of the present invention will become more apparent from the following detailed description when taken in conjunction with the accompanying drawings in which:

FIG. 1A illustrates the structure of an FCB;

FIG. 1B illustrates the structure of an SB;

FIG. 1C illustrates the structure of an NB;

FIG. 2 is a flowchart illustrating an operation for detecting the FCB block by block according to an embodiment of the present invention;

FIG. 3 is a block diagram of a GSM terminal according to another embodiment of the present invention;

FIG. 4 is a block diagram of a MODEM illustrated in FIG. 3 according to the second embodiment of the present invention; and

FIG. 5 is a flowchart illustrating an operation for detecting the FCB block by block according to the second embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0012] Preferred embodiments of the present invention will be described herein below with reference to the accompanying drawings. In the following description, well-known functions or constructions are not described in detail since they would obscure the invention in unnecessary detail.

[0013] In accordance with an embodiment of the present invention, to reduce the volume of computation in detecting the FCB, a terminal constructs a plurality of blocks each having a predetermined number of symbols and calculates the energy of each block, to thereby detect the FCB. A maximum error of one block is considered for SB reception.

[0014] FIG. 2 is a flowchart illustrating a block-based FCB detection operation according to an embodiment of the present invention.

[0015] Referring to FIG. 2, a GSM/GPRS terminal receives data of a predetermined length from a base station in step 11 and reads the symbols of one block (N) from the data in step 13. After processing the block in a bandpass filter (BPF) that passes a 67.7-kHz sine wave, the GSM/GPRS terminal calculates the energy of the processed block and stores the energy as a variable (E_block[N]) in step 15. The GSM/GPRS terminal determines whether the number of blocks read so far (N_block) is equal to the total number of blocks (N_block_per_window) in a window in step 17. If N_block is not equal to N_block_per_window, the GSM/GPRS terminal reads the next block (N+1) in step 19 and repeats steps 15 and 17. On the other hand, if N_block is equal to N_block_per_window, the GSM/GPRS terminal sums the energy values of the blocks by the following equation and stores the sum as the total energy of the current window (E_total).

$$E_total = \sum_{i=1}^{N_block} E[i]$$

(1)

[0016] As stated earlier, because the FCB is a sine wave at 67.7kHz lasting for one burst period, as the windows starts to cover the FCB, E_total increases. When the window covers the entire FCB, E_total has the highest value. As the FCB passes through the window, E_total decreases. Therefore, in step 23, the GSM/GPRS terminal determines whether E_total has reached its highest value and starts to decrease, while shifting the window block by block.

[0017] If E_total has not yet exceeded its highest value, the GSM/GPRS deletes the first received block of the window in step 20 and reads the next block in step 19. If E_total has exceeded its highest value, the GSM/GPRS terminal determines the previous block (N-1) as the last block of the FCB in step 25.

[0018] When detecting the end of the FCB, the GSM/GPRS can detect the start of the SB from the end of the FCB in step 27. In receiving the SB, the GSM/GPRS terminal considers a maximum error of one block.

[0019] Because the SB reception involves a maximum error of one block, the GSM/GPRS terminal receives the SB at least one more block of data. The resulting increase of the time required to receive the burst increases the operational time of signal chip sets including a MODEM/digital logic and an RF (Radio Frequency) chip set. As a result, power consumption and implementation complexity are increased, which in turn increases hardware and software complexity and delays processing.

[0020] Accordingly, in accordance with another embodiment of the present invention, a GSM/GPRS terminal determines a data block considered to include the end of the FCB among received data blocks and determines the end of the FCB using the symbols of the data block. FIG. 3 is a block diagram of a GSM/GPRS terminal according to the

second embodiment of the present invention.

[0021] Referring to FIG. 3, a controller 11 provides overall control to the GSM/GPRS terminal. An RF module 19 upconverts coded data received from a MODEM 18 to an RF signal and transmits the RF signal through an antenna (ANT). The RF module 19 also downconverts an RF signal received through the antenna, separates the downconverted signal by channel, and provides the channel signals to the controller 11 and a voice processor 20 through the MODEM 18. The MODEM 18 encodes and modulates transmission data and provides the modulated data to the RF module 19. The MODEM 18 also demodulates and decodes a signal received from the RF module 19 and provides the decoded signal to the controller 11 and the voice processor 20.

[0022] The data from the MODEM 18 provided to the controller 11 is data on a traffic channel, or a paging signal or a signaling signal on a control channel. The data output from the MODEM 18 to the voice processor 20 is voice data after a voice call is setup.

[0023] The voice processor 20 usually includes a vocoder. It is operated under the control of the controller 11. The voice processor 20 converts the coded voice data received from the MODEM 18 to an electrical voice signal through decoding and outputs the voice signal through a speaker (SPK). The speaker converts the electrical voice signal to audible sound. Also, the voice processor 20 encodes an electrical signal received from a microphone (MIC) and provides the coded signal to the MODEM 18.

[0024] A memory 17 may include a ROM (Read Only Memory) and a RAM (Random Access Memory). It is divided into an area for storing required for the control operation of the controller 11, an area for storing data by a user, and an area for temporarily storing data generated during the control operation. That is, the memory 17 is a randomly accessible and readable/writable memory. The memory 17 also stores control data in the area for storing data required for the control operation.

[0025] A display 15 is comprised of an LCD (Liquid Crystal Display) for displaying a letter or an icon/character to represent the present state of the GSM/GPRS terminal, a vibration motor, and an alarm lamp. Besides displaying the present state of the GSM/GPRS terminal, the LCD converts key input data entered by the user to letters or an icon. A keypad 13 is typically of a matrix structure. It includes digit keys for dialing and function keys for invoking functions.

[0026] In the thus-configured GSM/GPRS terminal, the MODEM 18 is provided with a sync information detector for detecting the FCB according to the present invention. The operation of the sync information detector will be detailed later.

[0027] FIG. 4 is a block diagram of the MODEM including the sync information detector for detecting the FCB according to the second embodiment of the present invention.

[0028] Referring to FIG. 4, a sync information detector 21 for the receiver of the GSM MODEM to which the present invention is applied is capable of measuring the strengths of multipath channel signals. It detects an accurate burst position using an FCB, the synchronization sequence of an SB, and the training sequence of an NB within a reception window.

[0029] An equalizer 23 measures the quality of the received signal based on the data received from the sync information detector 21. Alternatively, if a decoder 25 uses a soft-decision Viterbi algorithm, the equalizer 23 sums soft-decision values after convolutional decoding of the received data.

[0030] The decoder 25 decodes the coded data, outputs the decoding result, encodes the received data with the decoding result, and calculates the number of bit errors by comparing the coded data with the data before the decoding. The decoder 25 outputs the number of bit errors to a controller 29.

[0031] A CRC (Cyclic Redundancy Code) checker 27 checks the CRC of the decoded data received from the decoder 25 and determines whether the decoded data has a CRC error.

[0032] The controller 29 controls the operations of the equalizer 23, the decoder 25, and the CRC checker 27.

[0033] FIG. 5 is a flowchart illustrating an FCB detecting operation in the sync information detector according to the second embodiment of the present invention.

[0034] Referring to FIG. 5, the GSM/GPRS terminal receives data of a predetermined length including an FCB from a base station in step 51 and reads K symbols forming one block (N) from the received data in step 53. The GSM/GPRS terminal calculates the energy of each of the K symbols ($E_{\text{per_symbol}}[k]$) and stores the energy values in step 55. After processing the block in a BPF that passes a 67.7-kHz sine wave, the GSM/GPRS terminal calculates the energy of the processed block and stores the energy as a variable $E_{\text{block}}[N]$ in step 57. The GSM/GPRS terminal determines whether the number of blocks read so far (N_{block}) is equal to the total number of blocks in a window ($N_{\text{block_per_window}}$) in step 59. If N_{block} is not equal to $N_{\text{block_per_window}}$, the GSM/GPRS terminal reads the next block ($N+1$) in step 61 and repeats steps 55, 57 and 59.

[0035] When the energy of all the blocks of the window is completely calculated in step 59, the GSM/GPRS terminal sums the energy values of the blocks and stores the sum as the total energy of the window (E_{total}).

[0036] As stated earlier, because the FCB is a sine wave at 67.7kHz lasting for one burst period, as the windows starts to cover the FCB, E_{total} increases. When the window covers the entire FCB, E_{total} has the highest value. As the FCB passes through the window, E_{total} decreases. Therefore, in step 65, the GSM/GPRS terminal determines

whether E_{total} has reached its highest value and starts to decrease, while shifting the window block by block. If E_{total} has not yet exceeded its highest value, the GSM/GPRS deletes the first received block of the window in step 66 and reads the next block in step 61.

[0037] If E_{total} has exceeded its highest value, the GSM/GPRS terminal determines that the FCB includes (N_{block_per_window}-1) blocks and reads the energy value (E_{per_symbol}[K]) of the first symbol (K=1) of the current block [N] in step 67.

[0038] The GSM/GPRS terminal compares E_{per_symbol}[K] with a predetermined threshold (E_{threshold}) in step 69. E_{threshold} is the average of the energy values of the blocks included in the FCB.

$$E_{_threshold} = a \cdot \frac{\sum_{i=0}^{M-1} E[N-i-1]}{M}$$

(2)

where a is a significant variable that determines the accurate reception point of data. That is, if the current block is N, E_{threshold} is the average of the energy values of a predetermined number of blocks, and M and a (0<a≤1) vary with system characteristics.

[0039] If E_{per_symbol}[K] is less than E_{threshold} in step 69, the previous symbol [K-1] is determined as the last symbol of the FCB in step 75.

[0040] If E_{per_symbol}[K] is equal to greater than E_{threshold} in step 69, the GSM/GPRS terminal determines whether the current symbol index [K] is larger than the number of symbols per block (N_{symbol}) in step 71.

[0041] If [K] is equal to or less than N_{symbol}, the GSM/GPRS terminal reads the next symbol (K=K+1) in step 73 and returns to step 69.

[0042] If [K] is greater than N_{symbol}, the GSM/GPRS terminal determines the previous block [N-1] as the last block of the FCB in step 77 and thus detects the start of the SB from the end of the FCB with an accuracy of symbols in step 79.

[0043] While the invention has been shown and described with reference to certain preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

Claims

1. A method in a wireless terminal of detecting a frequency correction burst (FCB) for communication with a base station in a wireless communication terminal, comprising the steps of:

receiving a plurality of data blocks including a predetermined FCB, each having a plurality of data symbols; and determining a data block estimated to have the end of the FCB among the data blocks.

2. The method of claim 1, further comprising the step of determining as the end of the FCB a symbol previous to the first of symbols having energy values less than a predetermined threshold among the symbols of the determined data block.

3. The method of claim 1, wherein the data block determining step comprises the step of calculating the total energy of a window having a predetermined number of successive data blocks among the plurality of data blocks, while shifting the window block by block, and selecting the last data block of the window of which the total energy is decreased.

4. The method of claim 3, wherein the energy calculating step comprises the step of band-pass-filtering each of the predetermined number of data blocks to a predetermined frequency band determined by the FCB, calculating the energy of each of the filtered blocks, and obtaining the total energy by summing the block energies.

5. The method of claim 4, wherein the predetermined frequency band is between 0kHz and 67.7kHz.

6. The method of claim 1, wherein the threshold is the average of the energy values of a predetermined number of

blocks.

7. The method of claim 1, further comprising the step of, if the determined data block has no symbols having symbol energy values less than the threshold, determining a data block previous to the determined data block as the end of the FCB.

8. The method of claim 1, wherein the wireless communication terminal is a GSM/GPRS (Global System for Mobile Telecommunication/ General packet Radio Service) terminal
