(54) **Intake manifold**

(57) An intake manifold is disclosed. The intake manifold includes a first chamber (204) in fluid communication with a PCV line and disposed generally upstream of a second chamber (206). The chambers are designed to provide a long flow path for the moisture laden PCV gas and to help reduce the introduction of moisture or fluids

into the second chamber. This helps to prevent the ingestion of moisture or fluids by the combustion chambers of engine. An optional fluid blocker can also be used to trap fluids and help prevent those fluids from entering a cylinder port.

EP 1 757 780 A2

Description

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The present invention relates generally to motor vehicles, and in particular the present invention relates to an intake manifold for motor vehicles.

2. Description of Related Art

[0002] Modern internal combustion engines manage and recirculate crank case gases in an effort to control environmental pollution. Older internal combustion engines designed before adverse effects to the environment were seriously considered, used a tube to simply dump crank case gases into the atmosphere. This resulted in excessive environmental pollution, and systems designed to manage and control crank case gases were introduced. Current internal combustion engine designs use a PCV (Positive Crank Case Ventilation) system to control and manage the release of crank case gases. The PCV system uses a line disposed between the crank case and an intake manifold.

[0003] A PCV valve controls the release of crank case gases and vapors from the crank case into the intake manifold. This is done to preserve the air-fuel ratio and other conditions of the combustion gases in the intake manifold.

[0004] While known PCV systems have been effective in reducing environmental pollution, current PCV systems still suffer from a number of drawbacks. One major problem is moisture. Crank case gases and vapors can include moisture. Moisture is generally not a problem when diffused throughout the crank case gases and the intake manifold. However, when condensation occurs or when moisture levels increase, this can adversely affect engine performance. One particular problem is when condensation occurs and the moisture accumulates into droplets. These droplets can be ingested by a combustion chamber of a cylinder and severely impair combustion. Another problem occurs when the droplets freeze due to low temperature. When a frozen droplet is ingested by a cylinder, very serious problems can occur during the combustion process. Related PCV systems have not effectively addressed the problem of moisture and condensation.

SUMMARY OF THE INVENTION

[0005] An intake manifold that helps to control moisture and condensation is disclosed. The invention can be used in connection with a motor vehicle. The term "motor vehicle" as used throughout the specification and claims refers to any moving vehicle that is capable of carrying one or more human occupants and is powered by any form of energy. The term motor vehicle includes, but is not limited to cars, trucks, vans, minivans, SUV's, motorcycles, scooters, boats, personal watercraft, and aircraft.

[0006] In one aspect, the invention provides an intake manifold comprising a first chamber in fluid communication

with a PCV line and disposed generally upstream of a second chamber, the first chamber having a first moisture content and the second chamber having a second moisture content, and wherein the first moisture content is less than the second moisture content.

[0007] In another aspect, the first chamber is separated from the second chamber by a generally horizontal wall.

[0008] In another aspect, the horizontal wall is formed by a gasket.

[0009] In another aspect, the first chamber is formed by a groove formed in an upper cover associated with the intake manifold.

[0010] In another aspect, the second chamber is formed by a groove disposed in the intake manifold.

[0011] In another aspect, a gasket is disposed between a groove formed in the upper cover and a groove formed in the intake manifold, the groove in the upper cover forming the first chamber and the groove in the intake manifold forming the second chamber, wherein the gasket divides the first chamber from the second chamber.

[0012] In another aspect, gas received from the PCV line passes through a substantial portion of the first chamber before entering the second chamber.

[0013] In another aspect, the invention provides an intake manifold comprising a first chamber having an upstream portion in fluid communication with a PCV line and receiving PCV gas from the PCV line; a chamber hole disposed at a downstream portion of the first chamber, the chamber hole placing the first chamber in fluid communication with an upstream portion of a second chamber; and where the second chamber has at least one port hole configured to deliver PCV gas from the second chamber into a corresponding port.

[0014] In another aspect, the PCV gas in a portion of the first chamber travels in an opposite direction than the PCV gas in a corresponding portion of the second chamber.

[0015] In another aspect, a gasket separates the first chamber from the second chamber.

[0016] In another aspect, the chamber hole is disposed in the gasket.

[0017] In another aspect, at least one vent hole is disposed in the gasket.

[0018] In another aspect, the invention provides an intake manifold comprising a chamber configured to receive PCV gas; the chamber having a bottom; a port hole disposed in the bottom of the chamber, the port hole placing the chamber in fluid communication with a port; a fluid blocker associated with the bottom of the chamber, the fluid blocker extending an altitude above the bottom of the chamber; and where the fluid blocker prevents fluid below the altitude from entering the port hole.

[0019] In another aspect, the fluid blocker is integrally formed with the bottom of the chamber.

[0020] In another aspect, the fluid blocker includes a blocking portion and an insert portion, the insert portion

shaped to correspond with the port hole.

[0021] In another aspect, the fluid blocker includes a blocking portion having a slopped side.

[0022] In another aspect, the fluid blocker includes a blocking portion having a stepped side.

[0023] In another aspect, the fluid blocker includes a blocking portion having a curved side.

[0024] In another aspect, the fluid blocker includes an asymmetrical footprint.

[0025] In another aspect, the fluid blocker includes a generally symmetrical footprint.

[0026] Other systems, methods, features and advantages of the invention will be, or will become, apparent to one with skill in the art upon examination of the following figures and detailed description. It is intended that all such additional systems, methods, features and advantages be included within this description, be within the scope of the invention, and be protected by the following claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0027] The invention can be better understood with reference to the following drawings and description. The components in the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention. Moreover, in the figures, like reference numerals designate corresponding parts throughout the different views.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

15 **[0047]** Embodiments of the present invention help to manage and control moisture entrained with PCV gas. Figure 1 is an exploded view of a preferred embodiment of a manifold 100 and an upper cover 102. Preferably, upper cover 102 is configured to engage an upper portion 101 of manifold 100. In the embodiment shown in FIG. 1, manifold 100 includes a forward portion 150 that is configured to receive PCV line 104. As known in the art, the opposite end of PCV line 104 is connected to the interior of a crank case (not shown). PCV line 104 places the interior of the crank case in fluid communication with manifold 100 and is capable of delivering crank case gases through PCV line 104 to manifold 100.

20 **[0048]** Throughout this description, general direction and location terms are used. Some examples of these kinds of terms include forward, rearward, upper and lower. These terms are merely used to assist in describing the relative location of a certain item or portion. These terms are not intended to absolutely define the location or position of a certain item or part in any frame of reference or to the motor vehicle. This is particularly true in the case of a transverse engine. Forward or rearward relative to an engine block that is transversely mounted may actually refer to a lateral direction across the width of the motor vehicle.

25 **[0049]** Manifold 100 preferably includes provisions to receive PCV gases. In the embodiment shown in Figure 1, manifold 100 includes a manifold groove 110. Manifold groove 110 comprises a first manifold groove portion 112, a second manifold groove portion 114, and a third manifold groove portion 116. Preferably, first manifold groove 112 is in fluid communication with second manifold groove portion 114, and second manifold groove portion 114 is in fluid communication with third manifold groove portion 116. In the embodiment shown in Figure 1, first manifold groove portion 112 includes an upstream end in fluid communication with PCV line 104 and downstream end in fluid communication with second manifold groove portion 114. Preferably, first manifold groove portion 112 is disposed longitudinally with respect to manifold 100. Also, as shown in the embodiment of Figure 1, second manifold groove portion 114 is disposed generally laterally with respect to manifold 100 and third manifold groove portion 116 is disposed in a generally longi-

tudinally direction. In the embodiment shown in Figure 1, first manifold groove portion 112 is laterally spaced from third manifold groove portion 116. In some embodiments, first manifold groove portion 112 is generally parallel with third manifold groove portion 116.

[0050] Preferably, manifold 100 includes an upper cover 102. In some embodiments, a seal or joint packing is provided between manifold 100 and upper cover 102. In the embodiment shown in Figure 1, a gasket 106 is disposed between manifold 100 and upper cover 102. Gasket 106 can help to provide a seal between manifold 100 and upper cover 102.

[0051] Preferably, upper cover 102 includes provisions to receive PCV gas. In the preferred embodiment shown in Figure 1, upper cover 102 includes an upper cover groove 120. Preferably, upper cover groove 120 comprises a first upper cover groove portion 122, a second upper cover groove portion 124, and a third upper cover groove portion 126. Preferably, first upper cover groove portion 122 includes an upstream end configured to receive PCV gas from PCV line 104 and a downstream end in fluid communication with the upstream end of second upper cover groove portion 124. Preferably, the downstream end of the second upper cover groove portion 124 is in fluid communication with the upstream end of third upper cover groove portion 126.

[0052] In a preferred embodiment, upper cover groove 120 generally corresponds with manifold groove 110 after upper cover 102 has been assembled with manifold 100. A top view of the assembled manifold with upper cover 102 is shown in Figure 2. Section 3-3 provides a cross-sectional view of the assembled upper cover 102 and manifold 100. Referring to Figures 3 and 4, details of the assembled system can be observed.

[0053] After assembly, upper cover groove 120 and manifold groove 110 form a chamber 202. Gasket 106 is disposed between upper cover 102 and manifold 100 and can act to separate chamber 202 into two chambers: a first chamber 204 and a second chamber 206. In the embodiment shown in Figure 4, cover groove 120 forms first chamber 204 and manifold groove 110 forms second chamber 206. These two chambers help to create a unique flow path that can assist in managing and controlling moisture, fluid and/or water entrained with PCV gases.

[0054] Figure 5 is a schematic diagram of a preferred embodiment of chamber 202. A preferred flow path for the PCV gas can be observed in Figure 5. PCV gas 502 is delivered from PCV line 104 to first chamber 204. In the embodiment shown in Figure 5, a first section 222 of first chamber 204 receives incoming PCV gas 502. First section 222 of first chamber 204 is preferably formed by first cover groove portion 122 (see Figure 1). First section 222 of first chamber 204 is disposed in a generally longitudinally direction where the upstream end of first section 222 is disposed forward of the rear downstream end. The downstream end of first section 222 is in fluid communication with the second section 224 of first chamber

204. Preferably, second section 224 is formed by second cover groove portion 124 (see Figure 1). PCV gas 502 generally travels in a lateral direction 144 through second section 224 of first chamber 204. The downstream end of second section 224 is in fluid communication with the third section 226 of first chamber 204. Preferably, the third section 226 of first chamber 204 is formed by third cover groove portion 126 (see Figure 1). Third section 226 preferably extends in a generally longitudinally direction and, in the embodiment shown in Figure 5, third section 226 runs generally parallel with first section 222. The inlet of third section 226 is disposed in a generally rearward longitudinal direction 142 and the downstream end is disposed in a generally forward longitudinal direction 140.

[0055] Preferably, a chamber hole 132 is disposed near the downstream portion of third section 226 of first chamber 204. Preferably, chamber hole 132 places first chamber 204 in fluid communication with second chamber 206. In the embodiment shown in Figure 5, chamber hole 132 places the general downstream portion of third section 226 of first chamber 204 in fluid communication with the upstream portion of third section 236 of second chamber 204. Third section 236 has an upstream portion that is disposed in a generally forward longitudinal direction 140 and a downstream portion that is disposed in a generally rearward longitudinal direction 142. PCV gas 502 travels down the length of third section 236 of second chamber 206 to the second section 234 of second chamber 206.

[0056] Second section 234 of second chamber 206 is preferably laterally disposed and connects the downstream end of third section 236 with the upstream end of first section 232 of second chamber 206. Preferably, first manifold groove portion 112 forms first section 232 of second chamber 206 and second manifold groove portion 114 forms the second section 234 of second chamber 206 and third manifold groove portion 116 forms the third section 236 of second chamber 206.

[0057] This arrangement provides a flow path where PCV gas 502 is required to travel down the entire length of first chamber 204, travel from first chamber 204 to second chamber 206 through chamber hole 132 and then travel the entire length of second chamber 206. This long and tortuous flow path makes it difficult for water droplets, fluid or moisture to remain concentrated and cohesive throughout the entire flow path. Because of the lengthy flow path, fluid, moisture, and/or water droplets can evaporate or dissipate while traveling through first chamber 204 or second chamber 206. Also, fluid, moisture, and/or water droplets may become trapped in first chamber 204, never reaching second chamber 206.

[0058] The preferred arrangement shown in Figure 5 also helps to prevent ice from being ingested by the internal combustion engine. Icing can occur when condensation or water droplets freeze after the engine has been turned off. Because of the long and tortuous path shown schematically in Figure 5, it is unlikely that water

droplets will reach second chamber 206. If water droplets are present in first chamber 204, and those water droplets become frozen, the frozen water droplets in first chamber 204 do not pose a threat of being ingested by the cylinders of the internal combustion engine because of their location. After the engine has been turned on and running for a period of time, it is possible that the frozen water droplets will thaw and then eventually evaporate.

[0059] In some embodiments, additional holes besides chamber hole 132 can be provided. Figure 6 is an enlarged schematic diagram of a portion of first chamber 204 and second chamber 206. Figure 6 shows a portion of first section 222 of first chamber 204 and first section 232 of second chamber 206. One or more vent holes 602 and 604 can be provided through gasket 106. These vent holes 602 and 604 can be used to provide different flow conditions and to assist in moving PCV gas 502 from first chamber 204 to second chamber 206 without significantly impairing the moisture control benefits of the two chamber design. In an exemplary embodiment, one vent hole is provided for each cylinder port. This arrangement is shown in Figure 7 where six vent holes 702-712 are provided for each of the corresponding six ports. Gasket 106 may include additional holes to accommodate bolts that used to join upper cover 102 with manifold 100.

[0060] Some embodiments include an optional feature that prevent moisture, fluid or water from entering a port hole. FIGS. 8 and 9 are enlarged cross-sectional views of an upper portion 101 of manifold 100. As shown in Figure 8, manifold groove 110 includes a bottom 806. The bottom 806 of manifold groove 110 can include a port hole 804. Port hole 804 is used to deliver PCV gases from the second chamber 206 to port 802. As well known in the art, port 802 provides a gas with the appropriate amount of intake air or fresh air for a corresponding cylinder of an internal combustion engine. PCV gases mix with the intake air or fresh air in portion 802 and the PCV gases are eventually burned along with the air fuel mixture in the cylinder.

[0061] In some cases, fluid, moisture and/or water can reach the bottom 806 of manifold groove 110. If fluid reaches the bottom 806 of manifold groove 110, the fluid can enter port 802. To prevent this, some embodiments include an optional fluid blocker 904 as shown in Figure 9. In some embodiments, fluid blocker 904 includes a blocking portion 906. Blocking portion 906 can be raised a predetermined altitude above bottom 806 of manifold groove 110. As shown in Figure 9, this can help to provide a fluid trap so that fluid 902 is prevented from entering port hole 804.

[0062] In some embodiments, fluid blocker 904 is integrally formed with manifold 100, in other embodiments, fluid blocker 904 is separate from manifold 100. In one embodiment, shown in Figure 9, fluid blocker 904 includes an insert portion 908 that is shaped to correspond with port hole 804 and fit into port 804, and a blocking portion 906 connected to insert portion 908. A fluid blocker having this modular design can be retrofitted into ex-

isting manifolds.

[0063] Of course, fluid blocker 904 is not limited to the specific embodiment shown in Figure 9. Alternate designs are also possible. Figure 10 shows an alternate embodiment of fluid blocker 904. In this embodiment, fluid blocker 1002 has a tapered, conical shape with a flat, upper surface. Blocking portion 1002 can be integrally formed or be made as an insert with an insert portion 1004 as shown in Figure 10. Figure 15 shows a top view of blocking portion 1002. Figure 11 shows another alternative embodiment of fluid blocker 904. In this embodiment, fluid blocker 904 is a cylindrical member where the insert portion and the blocking portion are similar. A top view of this embodiment is shown in Figure 14.

[0064] While some embodiments include tapered sides, it is possible to provide side shapes of different designs. Figure 12 shows a fluid blocker 904 with a stepped side 1202 and Figure 13 shows an embodiment of a fluid blocker 904 with a sloped side 1302 that is non-linear. Any other suitable shape can be used for the side of fluid blocker 904. In addition to different shapes for the sides of fluid blocker 904, the overall shape or footprint of fluid blocker 904 can be different. In addition to the embodiments shown in FIGS. 14 and 15, FIGS. 16 and 17 show different embodiments of top view of fluid blocker 904. As shown in FIGS. 16 and 17, the blocking portions can be circular or oval and can be offset, and as shown in FIGS. 18 and 19, the blocking portions can include square or rectangular sides. The various shapes can be selected to fit into certain manifolds and to provide different flow blocking or fluid trapping characteristics.

[0065] In some embodiments, fluid blockers are provided on one or more ports, and in a preferred embodiment, all of the ports of a manifold include a fluid blocker.

[0066] In some embodiments, the optional fluid blockers can be used in combination with the two chamber flow path disclosed above. One or more of these features can be used to help manage and control the introduction of fluid, moisture and/or water into port 802, and ultimately prevent the cylinders of the internal combustion engine from ingesting fluid, moisture, water and/or ice.

[0067] While various embodiments of the invention have been described, the description is intended to be exemplary, rather than limiting and it will be apparent to those of ordinary skill in the art that many more embodiments and implementations are possible that are within the scope of the invention. Accordingly, the invention is not to be restricted except in light of the attached claims and their equivalents. Also, various modifications and changes may be made within the scope of the attached claims.

An intake manifold is disclosed. The intake manifold includes a first chamber in fluid communication with a PCV line and disposed generally upstream of a second chamber. The chambers are designed to provide a long flow path for the moisture laden PCV gas and to help reduce the introduction of moisture or fluids into the second chamber. This helps to prevent the ingestion of moisture

or fluids by the combustion chambers of engine. An optional fluid blocker can also be used to trap fluids and help prevent those fluids from entering a cylinder port.

Claims

1. An intake manifold comprising:

a first chamber in fluid communication with a PCV line and disposed generally upstream of a second chamber,
the first chamber having a first moisture content and the second chamber having a second moisture content, and

wherein the first moisture content is less than the second moisture content.

2. The intake manifold according to claim 1, wherein the first chamber is separated from the second chamber by a generally horizontal wall.

3. The intake manifold according to claim 2, wherein the horizontal wall is formed by a gasket.

4. The intake manifold according to claim 1, wherein the first chamber is formed by a groove formed in an upper cover associated with the intake manifold.

5. The intake manifold according to claim 1, wherein the second chamber is formed by a groove disposed in the intake manifold.

6. The intake manifold according to claim 1, wherein a gasket is disposed between a groove formed in the upper cover and a groove formed in the intake manifold, the groove in the upper cover forming the first chamber and the groove in the intake manifold forming the second chamber, wherein the gasket divides the first chamber from the second chamber.

7. The intake manifold according to claim 1, wherein gas received from the PCV line passes through a substantial portion of the first chamber before entering the second chamber.

8. An intake manifold comprising:

a first chamber having an upstream portion in fluid communication with a PCV line and receiving PCV gas from the PCV line;
a chamber hole disposed at a downstream portion of the first chamber, the chamber hole placing the first chamber in fluid communication with an upstream portion of a second chamber; and

wherein the second chamber has at least one port

hole configured to deliver PCV gas from the second chamber into a corresponding port.

9. The intake manifold according to claim 8, wherein the PCV gas in a portion of the first chamber travels in an opposite direction than the PCV gas in a corresponding portion of the second chamber.

10. The intake manifold according to claim 8, wherein a gasket separates the first chamber from the second chamber.

11. The intake manifold according to claim 10, wherein the chamber hole is disposed in the gasket.

12. The intake manifold according to claim 11, wherein at least one vent hole is disposed in the gasket.

13. An intake manifold comprising:

a chamber configured to receive PCV gas;
the chamber having a bottom;
a port hole disposed in the bottom of the chamber, the port hole placing the chamber in fluid communication with a port;
a fluid blocker associated with the bottom of the chamber, the fluid blocker extending an altitude above the bottom of the chamber; and

wherein the fluid blocker prevents fluid below the altitude from entering the port hole.

14. The intake manifold according to claim 13, wherein the fluid blocker is integrally formed with the bottom of the chamber.

15. The intake manifold according to claim 13, wherein the fluid blocker includes a blocking portion and an insert portion, the insert portion shaped to correspond with the port hole.

16. The intake manifold according to claim 13, wherein the fluid blocker includes a blocking portion having a sloped side.

17. The intake manifold according to claim 13, wherein the fluid blocker includes a blocking portion having a stepped side.

18. The intake manifold according to claim 13, wherein the fluid blocker includes a blocking portion having a curved side.

19. The intake manifold according to claim 13, wherein the fluid blocker includes an asymmetrical footprint.

20. The intake manifold according to claim 13, wherein the fluid blocker includes a generally symmetrical footprint.
