EP 2 293 620 B9

Description**TECHNICAL FIELD**

- 5 **[0001]** The present invention relates to data transmissions in a radio (wireless) communication system and, more particularly, to processing data units for transfer over the same channel in a radio communication system.

BACKGROUND ART

- 10 **[0002]** Recently, mobile communication systems have developed remarkably, but for high capacity data communication services, the performance of mobile communication systems cannot match that of existing wired communication systems. Accordingly, technical developments for IMT-2000, which is a communication system allowing high capacity data communications, are being made and standardization of such technology is being actively pursued among various companies and organizations.
- 15 **[0003]** A universal mobile telecommunication system (UMTS), which is a European-type IMT-2000 system, is a third generation mobile communication system that has evolved from a European standard known as Global System for Mobile communications (GSM) that aims to provide an improved mobile communication service based upon a GSM core network and wideband code division multiple access (W-CDMA) wireless connection technology.
- 20 **[0004]** In December 1998, the ETSI of Europe, the ARIB/TTC of Japan, the T1 of the United States, and the TTA of Korea formed a Third Generation
- [0005]** Partnership Project (3GPP), which is creating the detailed specifications of the UMTS technology.
- [0006]** Within the 3GPP, in order to achieve rapid and efficient technical development of the UMTS, five technical specification groups (TSG) have been created for performing the standardization of the UMTS by considering the independent nature of the network elements and their operations.
- 25 **[0007]** Each TSG develops, approves, and manages the standard specification within a related region. Among these groups, the radio access network (RAN) group (TSG-RAN) develops the standards for the functions, requirements, and interface of the UMTS terrestrial radio access network (UTRAN), which is a new radio access network for supporting W-CDMA access technology in the UMTS.
- [0008]** Figure 1 illustrates an exemplary basic structure of a general UMTS network. As shown in Figure 1, the UMTS is roughly divided into a terminal (or user equipment: UE), a UTRAN 100, and a core network (CN) 200.
- 30 **[0009]** The UTRAN 100 includes one or more radio network sub-systems (RNS) 110, 120. Each RNS 110, 120 includes a radio network controller (RNC) 111, and a plurality of Node-Bs 112, 113 managed by the RNC 111. The RNC 111 handles the assigning and managing of radio resources, and operates as an access point with respect to the core network 200.
- 35 **[0010]** The Node-Bs 112, 113 receive information sent by the physical layer of the terminal through an uplink, and transmit data to the terminal through a downlink. The Node-Bs 112, 113, thus, operate as access points of the UTRAN 100 for the terminal.
- [0011]** A primary function of the UTRAN 100 is forming and maintaining a radio access bearer (RAB) to allow communication between the terminal and the core network 200. The core network 200 applies end-to-end quality of service (QoS) requirements to the RAB, and the RAB supports the QoS requirements set by the core network 200. As the UTRAN 100 forms and maintains the RAB, the QoS requirements of end-to-end are satisfied. The RAB service can be further divided into an lu bearer service and a radio bearer service. The lu bearer service supports a reliable transmission of user data between boundary nodes of the UTRAN 100 and the core network 200.
- 40 **[0012]** The core network 200 includes a mobile switching center (MSC) 210 and a gateway mobile switching center (GMSC) 220 connected together for supporting a circuit switched (CS) service, and a serving GPRS support node (SGSN) 230 and a gateway GPRS support node 240 connected together for supporting a packet switched (PS) service.
- 45 **[0013]** The services provided to a specific terminal are roughly divided into the circuit switched (CS) services and the packet switched (PS) services. For example, a general voice conversation service is a circuit switched service, while a Web browsing service via an Internet connection is classified as a packet switched (PS) service.
- 50 **[0014]** For supporting circuit switched services, the RNCs 111 are connected to the MSC 210 of the core network 200, and the MSC 210 is connected to the GMSC 220 that manages the connection with other networks.
- [0015]** For supporting packet switched services, the RNCs 111 are connected to the SGSN 230 and the GGSN 240 of the core network 200. The SGSN 230 supports the packet communications going toward the RNCs 111, and the GGSN 240 manages the connection with other packet switched networks, such as the Internet.
- 55 **[0016]** Various types of interfaces exist between network components to allow the network components to transmit and receive information to and from each other for mutual communication therebetween. An interface between the RNC 111 and the core network 200 is defined as an lu interface. In particular, the lu interface between the RNCs 111 and the core network 200 for packet switched systems is defined as "lu-PS," and the lu interface between the RNCs 111 and

the core network 200 for circuit switched systems is defined as "lu-CS."

[0017] Figure 2 illustrates a structure of a radio interface protocol between the terminal and the UTRAN 100 according to the 3GPP radio access network standards.

[0018] As shown in Figure 2, the radio interface protocol has horizontal layers comprising a physical layer, a data link layer, and a network layer, and has vertical planes comprising a user plane (U-plane) for transmitting user data and a control plane (C-plane) for transmitting control information.

[0019] The user plane is a region that handles traffic information of the user, such as voice or Internet protocol (IP) packets, while the control plane is a region that handles control information for an interface of a network, maintenance and management of a call, and the like.

[0020] The protocol layers in Figure 2 can be divided into a first layer (L1), a second layer (L2), and a third layer (L3) based on the three lower layers of an open system interconnection (OSI) standard model. Each layer will be described in more detail as follows.

[0021] The first layer (L1), namely, the physical layer, provides an information transfer service to an upper layer by using various radio transmission techniques. The physical layer is connected to an upper layer called a medium access control (MAC) layer, via a transport channel. The MAC layer and the physical layer send and receive data with one another via the transport channel.

[0022] The second layer (L2) includes a MAC layer, a radio link control (RLC) layer, a broadcast/multicast control (BMC) layer, and a packet data convergence protocol (PDCP) layer.

[0023] The MAC layer provides an allocation service of the MAC parameters for allocation and re-allocation of radio resources. The MAC layer is connected to an upper layer called the radio link control (RLC) layer, via a logical channel.

[0024] Various logical channels are provided according to the kind of transmitted information. In general, when information of the control plane is transmitted, a control channel is used. When information of the user plane is transmitted, a traffic channel is used.

[0025] The MAC layer can be divided into a MAC-b sub-layer, a MAC-d sub-layer, a MAC-c/sh sub-layer, and a MAC-hs sub-layer according to the type of transport channel to be managed.

[0026] The MAC-b sub-layer manages a BCH (Broadcast Channel), which is a transport channel handling the broadcasting of system information.

[0027] The MAC-d sub-layer manages a dedicated channel (DCH), which is a dedicated transport channel for a specific terminal. Accordingly, the MAC-d sub-layer of the UTRAN is located in a serving radio network controller (SRNC) that manages a corresponding terminal, and one MAC-d sub-layer also exists within each terminal (UE).

[0028] The MAC-c/sh sub-layer manages a common transport channel, such as a forward access channel (FACH) or a downlink shared channel (DSCH), which is shared by a plurality of terminals. In the UTRAN, the MAC-c/sh sub-layer is located in a controlling radio network controller (CRNC). As the MAC-c/sh sub-layer manages the channel being shared by all terminals within a cell region, a single MAC-c/sh sub-layer exists for each cell region. Also, one MAC-c/sh sub-layer exists in each terminal (UE).

[0029] The MAC-hs sub-layer manages a HS-DSCH (High Speed Downlink Shared Channel), which is a downlink transport channel for high-speed data transmissions. In the UTRAN, one MAC-hs sub-layer is located at a Node-B in each cell region, and one MAC-hs sub-layer also exists in each terminal (UE).

[0030] The RLC layer supports reliable data transmissions, and performs a segmentation and concatenation function on a plurality of RLC service data units (RLC SDUs) delivered from an upper layer. When the RLC layer receives the RLC SDUs from the upper layer, the RLC layer adjusts the size of each RLC SDU in an appropriate manner upon considering processing capacity, and then creates certain data units with header information added thereto. The created data units are called protocol data units (PDUs), which are then transferred to the MAC layer via a logical channel. The RLC layer includes a RLC buffer for storing the RLC SDUs and/or the RLC PDUs.

[0031] The BMC layer schedules a cell broadcast message (referred to as a 'CB message', hereinafter) received from the core network, and broadcasts the CB messages to terminals located in a specific cell(s). The BMC layer of the UTRAN generates a broadcast / multicast control (BMC) message by adding information, such as a message ID (identification), a serial number, and a coding scheme to the CB message received from the upper layer, and transfers the BMC message to the RLC layer. The BMC messages are transferred from the RLC layer to the MAC layer through a logical channel, i.e., the CTCH (Common Traffic Channel). The CTCH is mapped to a transport channel, i.e., a FACH, which is mapped to a physical channel, i.e., a S-CCPCH (Secondary Common Control Physical Channel).

[0032] The PDCP (Packet Data Convergence Protocol) layer, as a higher layer of the RLC layer, allows the data transmitted through a network protocol (such as an IPv4 or IPv6) to be effectively transmitted on a radio interface with a relatively small bandwidth. To achieve this, the PDCP layer performs the function of reducing unnecessary control information used for a wired network, and this type of function is called, header compression.

[0033] There is a radio resource control (RRC) layer at a lowermost portion of the L3 layer. The RRC layer is defined only in the control plane, and handles the controlling of logical channels, transport channels, and physical channels with respect to setting, resetting, and releasing of radio bearers. The radio bearer service refers to a service that the second

layer (L2) provides for data transmission between the terminal and the UTRAN, and in general, setting the radio bearer refers to defining the protocol layers and the channel characteristics of the channels required for providing a specific service, as well as respectively setting substantial parameters and operation methods.

[0034] The RLC layer can belong to the user plane or to the control plane depending upon the type of layer connected at the upper layer of the RLC layer. That is, if the RLC layer receives data from the RRC layer, the RLC layer belongs to the control plane. Otherwise, the RLC layer belongs to the user plane.

[0035] The MAC header will now be described in greater detail. Figure 3 shows a structure of a MAC layer for the UTRAN. Figures 4 to 7 show structures of the MAC-d and MAC-c/sh sub-layer of the UTRAN, in which the square blocks show each function of the MAC layer. The primary functions thereof will now be described.

[0036] Typically, a protocol entity can receive data packets in the form of service data units (SDUs), and can send data packets in the form of protocol data units (PDUs). For example, in the UE for the uplink, an RLC layer sends data packets (RLC PDUs) to the MAC layer via a logical channel. The RLC PDUs sent by the RLC layer is received by the MAC layer in the form of MAC SDUs. The MAC layer further processes these MAC SDUs into MAC PDUs, which are then sent to the physical layer via a transport channel.

[0037] At the MAC layer, all MAC PDUs (Protocol Data Units) delivered to the physical layer via a transport channel during one transmission time interval (TTI) are defined as a Transport Block Set (TBS). A TBS may consist of one or several Transport Blocks (i.e., Data Blocks), each containing one MAC PDU. The Transport Blocks can be transmitted in the order as delivered from the RLC layer. When the MAC layer performs multiplexing of RLC PDUs from different logical channels, the order of all Transport Blocks originating from the same logical channel can be the same as the order of the sequence delivered from the RLC layer. The order of the different logical channels in a TBS is set by the MAC protocol.

[0038] The MAC layer performs the function of identifying the UEs and the logical channels. There are two main reasons for identification: first, the UEs need to be distinguished from one another because many UEs share a common transport channel; and second, the logical channels must be distinguished from one another because logical channel multiplexing is performed. In case of uplink, without any identification, the receiving end (i.e., the UTRAN) cannot determine which UE sent the data units and cannot determine which logical channel was used in sending the data units.

[0039] For identification, the MAC layer adds one or more of the following parameters; a TCTF (target channel type field), a UE-ID type, a UE-ID, and/or a C/T(Control/Traffic) field, to form a header of the MAC PDU. According to the related art, a MAC header is added to each MAC SDU (Service Data Unit) within a MAC PDU. That is, even those MAC SDUs that are transmitted during the same TTI have different MAC headers added thereto. Figure 8 shows a format of the MAC PDU.

[0040] Identification of the UE (i.e., a UE-ID field) is necessary when a dedicated logical channel (such as DCCH or DTCH) is mapped to a common transport channel (such as the RACH, FACH, CPCH, DSCH or USCH). To achieve this, the MAC layer adds a radio network temporary identity (RNTI) (which is a type of identification information for a UE) to the UE-ID field of the header. There are three types of RNTIs: a U-RNTI (UTRAN RNTI), a C-RNTI (Cell RNTI), and a DSCH-RNTI. Thus, a UE-ID type field that indicates the type of RNTI used is also transmitted as part of the header.

[0041] There are two kinds of identifications for the logical channel: one is a TCTF, and the other is a C/T field. The TCTF is required for the transport channel where a dedicated logical channel (such as a DCCH and DTCH) can be mapped together with other logical channels. That is, for FDD (frequency division duplex), a TCTF is required only for the RACH and the FACH, while for TDD (time division duplex), a TCTF is also required for the USCH and the DSCH.

[0042] Referring to FDD, the TCTF for the FACH identifies that the mapped logical channel is a BCCH, a CCCH, or a CTCH, or is a dedicated logical channel (DCCH or DTCH), while the TCTF for the RACH identifies that the mapped logical channel is a CCCH or a dedicated logical channel. However, the TCTF does not identify the particular type of dedicated logical channel that was used.

[0043] The identification of the dedicated logical channel is provided by the C/T field. The reason for this is that, first, unlike other logical channels, several dedicated logical channels can be mapped to one transport channel, and, second, the dedicated logical channel is handled by the MAC-d of the SRNC, while other logical channels are handled by the MAC-c/sh of the CRNC.

[0044] Each of the dedicated logical channels mapped to one transport channel has a logical channel identifier, which is used as the C/T field value. However, if only one dedicated logical channel is mapped to one transport channel, the C/T field is not necessary.

[0045] Table 1 below shows the different identifiers of a MAC header that are used according to the mapping relationship between logical channels and transport channels for FDD. In Table 1, a C/T field exists when several dedicated logical channels (DCCH or DTCH) are mapped. Also, "N" indicates that there is no header, "-" indicates that there is no mapping relationship, and "UE-ID" indicates that both a UE-ID field and a UE-ID type field exist. A UE-ID field always exists together with a UE-ID type field.

[Table 1]

	DCH	RACH	FACH	DSCH	CPCH	BCH	PCH
DCCH or DTCH	C/T	TCTF UE-ID C/T	TCTF UE-ID C/T	UE-ID C/T	UE-ID C/T	-	-
BCCH	-	-	TCTF	-	-	N	-
PCCH	-	-	-	-	-	-	N
CCCH	-	TCTF	TCTF	-	-	-	-
CTCH	-	-	TCTF	-	-	-	-

[0046] In the related art, when the DTCH or DCCH logical channels are mapped to certain transport channels (RACH, FACH, DSCH, CPCH), both a UE-ID and a UE-ID type are added by the MAC layer to the header of every MAC SDU. An example is given in document WO 01/69952 A1, which describes a method for concatenating service data units in a MAC layer comprising two MAC sub-Layers.

[0047] In this manner, if there is more than one MAC SDU to be transmitted during one TTI and the same MAC header is added to every MAC SDU, the related art technique redundantly attaches a MAC header to every MAC SDU during one TTI. In particular, when the DTCH or DCCH data is transmitted over a common transport channel such as the RACH, the terminal identifier (UE-ID) field of 16 or 32 bits and the UE-ID type field of 2 bits are redundantly added to every MAC SDU.

[0048] The present inventors realized that the related art is disadvantageous because the adding of the same UE-ID and UE-ID type to each header of each MAC SDU is repetitive and unnecessary. Accordingly, due to the redundancy in transmitting protocol data units, the related art is quite ineffective and wastes much radio resources.

DISCLOSURE OF THE INVENTION

[0049] Therefore, an object of the present invention is to provide a data transmission method of a mobile communication system capable of concatenating two or more service data units to be transferred over the same channel into one protocol data unit having a single header in order to avoid redundancy of header information.

[0050] To achieve at least the above object in whole or in parts, there is provided a mobile communication system comprising: a protocol layer for generating a protocol data unit (PDU) comprising a payload formed by concatenating one or more service data units and having a header added thereto, and transferring the PDU to a lower layer a transmission time interval (TTI).

[0051] Preferably, the service data units are received from an upper layer of the protocol layer.

[0052] Preferably, the service data units have the same destination address.

[0053] Preferably, the service data units are transferred over the same transport channel.

[0054] Preferably, the protocol layer is a medium access control (MAC) sub-layer located below a MAC sub-layer managing a dedicated resource.

[0055] Preferably, the protocol layer is a medium access control (MAC) sub-layer managing a common resource.

[0056] Preferably, the header includes information regarding an identifier (UE-ID) of a terminal.

[0057] Preferably, the header further includes information regarding the type of terminal identifier.

[0058] Preferably, the header includes information regarding a logical channel.

[0059] To achieve at least these advantages in whole or in parts, there is further provided a mobile communication system including a protocol layer for receiving one protocol data unit (PDU) from a lower layer at a transmission time interval (TTI), detecting a header from the received PDU, and disassembling a payload comprising one or more service data unit (SDUs).

[0060] Preferably, the protocol data units are received over the same transport channel.

[0061] Preferably, the protocol layer is a medium access control (MAC) sub-layer located below a MAC sub-layer managing a dedicated resource.

[0062] Preferably, the protocol layer is a medium access control (MAC) sub-layer managing a common resource.

[0063] Preferably, if the header includes terminal identifier information, the protocol layer checks whether the terminal identifier is identical to an identifier of a terminal to which the protocol layer itself belongs to, and if the two terminal identifiers are identical, the protocol layer transmits the disassembled SDUs to an upper layer entity that the header information indicates. If however, the two terminal identifiers are not identical, the protocol layer discards the received

PDU.

[0064] To achieve at least these advantages in whole or in parts, there is further provided a protocol data transmission method including: concatenating one or more service data units (SDUs) received from an upper layer to constitute a payload; adding a header to the payload to generate a PDU; transferring the generated PDU to a lower layer for a transmission time interval (TTI); and transmitting the generated PDU to a receiving end through a physical layer service.

[0065] To achieve at least these advantages in whole or in parts, there is further provided a protocol data receiving method including: receiving one protocol data unit (PDU) from a lower layer at a transmission time interval (TTI); separating a header and a payload from the received PDU; disassembling the payload into one or more service data units (SDUs); and transferring the disassembled SDUs to an upper layer.

[0066] Additional advantages, objects, and features of the invention will be set forth in part in the description which follows and in part will become apparent to those having ordinary skill in the art upon examination of the following or may be learned from practice of the invention. The objects and advantages of the invention may be realized and attained as particularly pointed out in the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0067] The invention will be described in detail with reference to the following drawings in which like reference numerals refer to like elements wherein:

Figure 1 illustrates the UMTS network architecture;
 Figure 2 illustrates the radio interface protocol architecture between the terminal and UTRAN that are based upon the 3GPP wireless access network standards;
 Figure 3 illustrates a structure of a MAC layer of a general UTRAN;
 Figure 4 illustrates a structure of a MAC-c/sh sub-layer of a general terminal (UE);
 Figure 5 illustrates a structure of a MAC-c/sh sub-layer of the general UTRAN;
 Figure 6 illustrates a structure of a MAC-d sub-layer of the general terminal (UE);
 Figure 7 illustrates a MAC-d sub-layer of the general UTRAN;
 Figure 8 illustrates a format of a general MAC PDU;
 Figure 9 illustrates a format of a MAC-c/sh header in accordance with one embodiment of the present invention;
 Figures 10A to 10E illustrate formats of a MAC-c/sh header in accordance with one embodiment of the present invention;
 Figures 11A and 11B illustrate formats of the MAC-c/sh SDU in accordance with one embodiment of the present invention;
 Figure 12 illustrates a structure of the MAC-c/sh sub-layer in accordance with one embodiment of the present invention;
 Figure 13 illustrates a structure of the MAC-c/sh sub-layer of the UTRAN in accordance with one embodiment of the present invention; and
 Figure 14 illustrates a transmission process of the MAC-c/sh in accordance with one embodiment of the present invention.

BEST MODE FOR CARRYING OUT THE INVENTION

[0068] For exemplary purposes only, the features of the present invention will be described herebelow with respect to a MAC-c/sh, a particular type of MAC layer entity. However, the teachings and suggestions of the present invention can also be applied to other appropriate types of MAC layer entities, in particular those MAC entities that are currently under development for handling high-speed data packet transmissions. For example, it is foreseen that the teachings and suggestions of the present invention would be applicable to various enhancements of uplink dedicated channel techniques.

[0069] As high-speed data packet transmission technology evolves with the aim of using minimal radio access and network resources to handle large amounts of data, the motivation to apply the teachings and suggestions of the present invention and variations thereof that prevent the waste of radio access and network resources is clearly provided to those having ordinary skill in the art.

[0070] Also, it should be noted that the present invention will be described with respect to certain types of logical channels, transport channels and physical channels. However, the teachings and suggestions of the present invention are equally applicable to various logical channels (dedicated, common, etc.), which are mapped to various transport channels (dedicated, common, etc.), which are then again mapped to various physical channels (dedicated, common, etc.).

[0071] Figure 9 illustrates a format of a MAC-c/sh header in accordance with one embodiment of the present invention.

As shown in Figure 9, one PDU of the MAC-c/sh is transmitted through a transport channel at a TTI. Each PDU comprises one MAC-c/sh header and one or more of MAC-c/sh SDUs. That is, a payload of the MAC-c/sh PDU includes one or more of MAC-c/sh SDUs. The MAC-c/sh PDU can be considered to be the same as a MAC PDU. One MAC PDU is transmitted to the transport channel during one TTI. All the MAC-c/sh SDUs included in the MAC PDU should be related

to one terminal.

[0072] Unlike the related art, according to the transmission method in accordance with the present invention, since only one UE-ID field and only one UE-ID type field are transmitted during one TTI, radio (wireless) resources can be saved.

[0073] Figures 10A to 10E illustrate formats of a MAC-c/sh header in accordance with one embodiment of the present invention, showing types of MAC-c/sh header formats for implementing the present invention.

[0074] In the drawings, a TCTF is a field indicating a type of a logical channel. Specifically, the TCTF is an indicator indicating whether a logical channel that has transferred a corresponding MAC-c/sh SDU is a CCCH, a CTCH or a DCCH/DTCH.

[0075] A UE-ID type is a field indicating a type of an UE-ID included in a header. Specifically, the UE-ID type identifies a C-RNTI, a U-RNTI, a DSCH-RNTI, a terminal group indicator or a broadcast and multicast service indicator.

[0076] A UE-ID is a field including information for identifying a terminal (UE) that transmits a corresponding MAC-c/sh SDU, information for identifying a specific terminal group or information for identifying a specific service related to a corresponding UE.

[0077] The format of the MAC-c/sh header as shown in Figure 10A can be used when a logical channel used in transmitting the MAC-c/sh SDU is a dedicated logical channel, and a common transport channel uses various types of UE-IDs and mapped to several types of logical channels.

[0078] The format of the MAC-c/sh header as shown in Figure 10B can be used when a logical channel used in transmitting the MAC-c/sh SDU is a dedicated logical channel, and a common transport channel uses various types of UE-IDs.

[0079] The format of the MAC-c/sh header as shown in Figure 10C can be used when a logical channel used in transmitting the MAC-c/sh SDU is a dedicated logical channel, and a common transport channel uses one type of UE-ID.

[0080] The format of the MAC-c/sh header as shown in Figure 10D can be used when a common transport channel used in transmitting the MAC-c/sh SDU is mapped to various types of logical channels.

[0081] The format of the MAC-c/sh header as shown in Figure 10E can be used when a logical channel used in transmitting the MAC-c/sh SDU is a dedicated logical channel, and a common transport channel uses one type of UE-ID and is mapped to various types of logical channels.

[0082] Figures 11A and 11B illustrate formats of the MAC-c/sh SDU in accordance with one embodiment of the present invention, showing various types of MAC-c/sh SDU formats for implementing the present invention.

[0083] A format of the MAC-c/sh SDU as shown in Figure 11A comprises only an RLC PDU and can be used when a logical channel used in transmitting the MAC-c/sh SDU is a dedicated logical channel and only one such dedicated logical channel exists. That is, one dedicated logical channel is mapped to one transport channel. The RLC PDU is equivalent to the MAC-c/sh SDU.

[0084] A format of the MAC-c/sh SDU as shown in Figure 11B is used when a logical channel used in transmitting the MAC-c/sh SDU is a common logical channel. In case of the common logical channel, no multiplexing takes place, thus the MAC-c/sh SDU is the same as the RLC PDU. Here, the MAC-c/sh SDU is the same as the MAC-d PDU.

[0085] Figure 12 illustrates a structure of the MAC-c/sh sub-layer in accordance with one embodiment of the present invention, and Figure 13 illustrates a structure of the MAC-c/sh sub-layer of the UTRAN in accordance with one embodiment of the present invention.

[0086] As shown in Figures 12 and 13, in the present invention, a function of concatenating (and disassembling) of the MAC-c/sh SDU is added to the related art MAC-c/sh sub-layer in the UTRAN and terminal (UE), respectively. For a downlink transport channel, the MAC-c/sh of the UTRAN performs a function of concatenating the MAC-c/sh SDU, and the MAC-c/sh of the terminal performs a function of disassembling the MAC-c/sh SDU. Meanwhile, for an uplink transport channel, the MAC-c/sh of the terminal performs a function of concatenating the MAC-c/sh SDU and the MAC-c/sh of the UTRAN performs a function of disassembling the MAC-c/sh SDU.

[0087] Figure 14 illustrates a transmission process of the MAC-c/sh in accordance with one embodiment of the present invention.

[0088] For downlink transmission, a transmitting end is the UTRAN and a receiving end is the terminal. Meanwhile, for uplink transmission, the transmitting end is the terminal and the receiving end is the UTRAN. In Figure 14, an upper layer refers to a layer positioned at an upper portion of the MAC-c/sh. Namely, the upper layer is the MAC-d if a dedicated logical channel is used, while the upper layer is the RLC if a common logical channel is used.

[0089] First, when a MAC-c/sh SDU is transferred from an upper layer 310 to a MAC-c/sh 320 (step S10), the MAC-c/sh 320 concatenates a plurality of MAC-c/sh SDUs to be transmitted during one TTI to form a payload, and adds a MAC-c/sh header to the payload to generate one MAC-c/sh PDU (step S20).

[0090] The MAC-c/sh 320 of the sending end transfers one MAC-c/sh PDU to a MAC-c/sh 330 of the receiving end

through a physical layer service at every TTI (step S30).

[0091] The MAC-c/sh 330 removes the MAC-c/sh header from the received MAC-c/sh PDU, and disassembles the concatenated MAC-c/sh SDUs (step S40). And then, the MAC-c/sh 330 transfers the disassembled MAC-c/sh SDUs to an upper layer 340 (step S50).

[0092] If terminal identifier (UE-ID) information is included in the MAC-c/sh header, the MAC-c/sh 330 checks whether the terminal identifier (UE-ID) included in the header is identical to an identifier (UE-ID) of a terminal to which the MAC-c/sh 330 itself belongs to. If the two terminal identifiers are identical, the MAC-c/sh 330 transfers the disassembled upper layer PDUs to an upper layer entity that the header information indicates. Thereafter, the MAC-c/sh 330 transfers the MAC-c/sh SDUs to the upper layer via a logical channel that the header information indicates. If, however, the two terminal identifiers are not identical, the MAC-c/sh 330 discards the received MAC-c/sh PDU.

[0093] One embodiment of the present invention pertains to a method of processing protocol data by a terminal comprising concatenating two or more data units received from an upper layer for one transmission time interval (TTI); and adding a single header to the concatenated data units.

[0094] Another embodiment of the present invention pertains to a method of processing data blocks by user equipment in radio communications, the method comprising detecting two or more data blocks sent from a higher layer entity; performing concatenation on the detected data blocks to form a concatenated data block; adding a single header to the concatenated data block; and sending the header-added concatenated data block to a lower layer entity.

[0095] Another embodiment of the present invention pertains to a method of processing data units comprising receiving one or more service data units from an upper layer; concatenating the service data units to form a single medium access control payload (MAC payload); adding a single header to the medium access control payload (MAC payload) to form a medium access control protocol data unit (MAC PDU); and sending the medium access control protocol data unit (MAC PDU) to a lower layer.

[0096] Another embodiment of the present invention pertains to a common medium access control (MAC) layer for a user equipment comprising a first entity to receive per transmission time interval (TTI) one or more service data units from an upper layer; and a second entity to concatenate two or more service data units into a medium access control payload, to add a single header to the medium access control payload to form a medium access control protocol data unit, and to send the medium access control protocol data unit to a lower layer.

INDUSTRIAL APPLICABILITY

[0097] As so far described, the present invention newly defines the structure of protocol data unit transmitted via a transport channel, and a transmission method is provided in order to avoid redundant attachment of a terminal identifier (UE-ID) and a UE-ID type information.

[0098] In addition, in the present invention, because only one terminal identifier (UE-ID) and the UE-ID type are added during one TTI, the efficiency of data transmission is increased and waste of the radio resources is remarkably reduced.

[0099] In particular, the present invention being implemented in a terminal (UE) results in significant reductions in the amount of radio resources that need to be used on the uplink. As minimizing the required battery power and signal processing for the terminal (UE) is always desirable, the present invention advantageously provides more efficient uplink data transmissions.

[0100] The foregoing embodiments and advantages are merely exemplary and are not to be construed as limiting the present invention. The present teachings can be readily applied to other types of methods and apparatuses. The description of the present invention is intended to be illustrative, and not to limit the scope of the claims. Many alternatives, modifications, and variations will be apparent to those skilled in the art. In the claims, means-plus-function clauses are intended to cover the structure described herein as performing the recited function and not only structural equivalents but also equivalent structures.

It follows a list of embodiments

[0101]

1. A method of processing data units by a terminal comprising: concatenating two or more data units received from an upper layer for one transmission time interval (TTI) ; and adding a single header to the concatenated data units.

2. The method of embodiment 1, wherein the upper layer is a MAC sub- layer managing resources dedicated to a specific terminal.

3. The method of embodiment 1, further comprising transmitting the header- added concatenated data units via an uplink channel.

4. The method of embodiment 3, wherein the uplink channel is a random access channel or a dedicated channel.
5. The method of embodiment 3, wherein the transmitting via the uplink channel occurs in-band.
- 5 6. The method of embodiment 1, wherein the header comprises terminal identifier information.
7. The method of embodiment 6, wherein the terminal identifier information comprises a terminal identification (UE-ID) and a terminal identification type (UE-ID type).
- 10 8. A method of processing data blocks by user equipment in radio communications, the method comprising: detecting two or more data blocks sent from a higher layer entity; performing concatenation on the detected data blocks to form a concatenated data block ; adding a single header to the concatenated data block ; and sending the header-added concatenated data block to a lower layer entity.
- 15 9. The method of embodiment 8, wherein the higher layer entity is a MAC entity managing resources dedicated to a specific terminal.
10. The method of embodiment 8, wherein the detecting step is performed for one transmission time interval (TTI).
- 20 11. The method of embodiment 8, wherein the steps are performed via an uplink channel.
12. The method of embodiment 11, wherein the uplink channel is a random access channel or a dedicated channel.
13. The method of embodiment 11, wherein the steps performed via the uplink channel occurs in-band.
- 25 14. The method of embodiment 8, wherein the header comprises terminal identifier information.
15. The method of embodiment 14, wherein the terminal identifier information comprises a terminal identification (UE-ID) and a terminal identification type (UE-ID type).
- 30 16. A method of processing data units comprising: receiving a one or more service data units from an upper layer ; concatenating the received service data units to form a single medium access control payload ; adding a single header to the medium access control payload to form a medium access control protocol data unit; and sending the medium access control protocol data unit to a lower layer.
- 35 17. The method of embodiment 16, wherein the upper layer is a MAC sub- layer managing resources dedicated to a specific terminal.
18. The method of embodiment 16, wherein the concatenating is performed on service data units received during a single transmission time interval (TTI).
- 40 19. The method of embodiment 16, wherein the steps are performed via an uplink channel.
20. The method of embodiment 19, wherein the uplink channel is a random access channel or a dedicated channel.
- 45 21. The method of embodiment 19, wherein the steps performed via the uplink channel occurs in-band.
22. The method of embodiment 16, wherein the header comprises terminal identifier information.
- 50 23. The method of embodiment 22, wherein the terminal identifier information comprises a terminal identification (UE-ID) and a terminal identification type (UE-ID type).
24. A medium access control (MAC) layer for a user equipment comprising : a first entity to receive per transmission time interval (TTI) one or more of service data units from an upper layer ; and a second entity to concatenate two or more received service data units into a medium access control payload and to add a single header to the medium access control payload to form a medium access control protocol data unit, and then to send the medium access control protocol data unit to a lower layer.
- 55

25. The method of embodiment 24, wherein the MAC layer is a MAC sublayer located below a MAC sub-layer managing resources dedicated to a specific terminal.

26. The method of embodiment 24, wherein the upper layer is a MAC sublayer managing resources dedicated to a specific terminal.

27. A transmission system for mobile communications comprising: a protocol layer for generating a protocol data unit (PDU) comprising a payload formed by concatenating two or more service data units (SDUs) and adding a single header thereto, and for transferring the protocol data unit (PDU) to a lower layer at a transmission time interval (TTI).

28. The system of embodiment 27, wherein the header includes information on an identifier of a terminal (UE-ID).

29. The system of embodiment 28, wherein the header additionally includes information on a type of the terminal identifier (UE-ID type).

30. The system of embodiment 27, wherein the header includes information on a logical channel.

31. The system of embodiment 27, wherein the PDU is transmitted to a lower layer through a common transport channel.

32. The system of embodiment 27, wherein the SDUs are transmitted from an upper layer through a dedicated logical channel.

33. The system of embodiment 27, wherein the SDUs have the same destination address.

34. The system of embodiment 27, wherein the protocol layer is a medium access control (MAC) sub-layer below a MAC sub-layer managing resources dedicated to a specific terminal.

35. The system of embodiment 34, wherein the MAC sub-layer is a MAC- c/sh sub-layer and the PDU is a MAC- c/sh PDU.

36. The system of embodiment 34, wherein the MAC sub-layer transmits only one PDU to a lower layer for a transmission time interval (TTI).

37. The system of embodiment 34, wherein the SDU is a MAC-c/sh service data unit (SDU).

38. The system of embodiment 27, wherein the PDU is transferred to a receiving end by using a physical layer service.

39. A protocol data transmission method in a mobile communication system comprising: concatenating two or more service data units (SDUs) for a transmission time interval (TTI) to constitute a payload ; adding a header to the payload to generate a protocol data unit (PDU); transferring the generated PDU to a lower layer ; and transmitting the transferred PDU to a receiving end via a physical layer service.

40. The method of embodiment 39, wherein the header includes information on an identifier of a terminal (UE-ID).

41. The method of embodiment 40, wherein the header additionally includes information on a type of the terminal identifier.

42. The method of embodiment 39, wherein the header includes information on a logical channel.

43. The method of embodiment 39, wherein the PDU is transferred to a lower layer via a common transport channel.

44. The method of embodiment 39, wherein the SDUs are transmitted from an upper layer through a dedicated logical channel.

45. The method of embodiment 39, wherein the SDUs have the same destination address.

46. The method of embodiment 39, wherein the SDU is a MAC-c/sh service data unit (SDU).

47. A receiving system of a mobile communication comprising: a protocol layer for receiving one protocol data unit (PDU) from a lower layer at a transmission time interval (TTI), detecting a header from the received PDU, and disassembling a payload comprising protocol data units of a plurality of upper layers.

48. The method of embodiment 47, wherein the upper layers are MAC sublayers managing resources dedicated to a specific terminal.

49. A protocol data transmission method in a mobile communication system comprising: receiving one protocol data unit (PDU) from a lower layer at a transmission time interval (TTI); separating a header and a payload from the received PDU; disassembling the concatenated service data units (SDUs) of the payload; and transferring the disassembled SDUs to an upper layer.

50. The method of embodiment 49, wherein the header includes information on an identifier of a terminal (UE-ID).

51. The method of embodiment 50, wherein the header additionally includes information on a type of the terminal identifier.

52. The method of embodiment 49, wherein if the header includes terminal identifier information, it is checked whether the terminal identifier is identical to an identifier of a terminal to which the protocol layer itself belongs to.

53. The method of embodiment 52, wherein if the two terminal identifiers are identical, the disassembled SDUs are respectively transferred to an upper layer entity that the header information indicates.

54. The method of embodiment 52, wherein if the two terminal identifiers are identical, the disassembled SDUs are transferred to an upper layer through a logical channel that the header information indicates.

55. The method of embodiment 52, wherein if the two terminal identifiers are not identical, the received PDU is discarded.

Claims

1. A terminal for uplink processing in a wireless communication system, the terminal comprising:

a receiving module for receiving a plurality of MAC (Medium Access Control) service data units;
a concatenating module for concatenating the plurality of MAC service data units;
a header module for adding a MAC header to the plurality of concatenated MAC service data units to produce a MAC protocol data unit, the MAC header comprising a channel identifier; and
a transmitting module for transmitting the MAC protocol data unit to a lower entity through a transport channel, wherein the plurality of MAC service data units are received by the receiving module in a MAC entity having a first MAC sub-entity and a second MAC sub-entity,
wherein the channel identifier identifies a logical channel which is located between a RLC (Radio Link Control) entity and the MAC entity, and the transport channel is located between the MAC entity and the lower entity, wherein the plurality of concatenated MAC service data units are formed in the second MAC sub-entity, wherein the first MAC sub-entity is a MAC-d sub-entity for a dedicated channel and the second MAC sub-entity is located below the MAC-d sub-entity, and
wherein the first MAC sub-entity and the second MAC sub-entity are capable of uplink data processing.

2. The terminal of claim 1, wherein the plurality of MAC service data units are received from at least one common logical channel.

3. The terminal of claim 1, wherein the plurality of MAC service data units are received from at least one dedicated logical channel.

4. The terminal of claim 1, wherein the channel identifier determines whether the plurality of MAC service data units are being sent from a common logical channel or a dedicated logical channel.

5. The terminal of claim 1, wherein the channel identifier determines a type of the logical channel.
6. The terminal of claim 1, wherein the MAC header further comprises a data identifier that determines one of a terminal transmitting the plurality of MAC service data units, a terminal group transmitting the plurality of MAC service data units, and a service related to the plurality of MAC service data units.
7. The terminal of claim 6, wherein the header module is configured to include a type identifier in the MAC header, the type identifier indicating a type of the data identifier being transmitted.
8. The terminal of claim 1, wherein the MAC protocol data unit is transmitted through the transport channel which is one of a random access channel and a dedicated channel in one TTI (Transmission Time Interval).
9. A system for uplink processing in a wireless communication network, the system comprising:
a receiving module for receiving a MAC (Medium Access Control) protocol data unit from a lower entity through a transport channel, the MAC protocol data unit including a MAC header and a plurality of MAC service data units which are concatenated;
an extracting module for extracting the MAC header from the received MAC protocol data unit, the MAC header comprising a channel identifier; and
a disassembling unit for disassembling the plurality of MAC service data units and transmitting the individual MAC service data units to a RLC (Radio Link Control) entity,
wherein the MAC protocol data unit is received by the receiving module in a MAC entity of the system having a first MAC sub-entity and a second MAC sub-entity,
wherein the channel identifier identifies a logical channel which is located between the RLC entity and the MAC entity, and the transport channel is located between the MAC entity and the lower entity, and
wherein the plurality of MAC service data units are disassembled in the second MAC sub-entity,
wherein the first MAC sub-entity is a MAC-d sub-entity for a dedicated channel and the second MAC sub-entity is located below the MAC-d sub-entity, and
wherein the first MAC sub-entity and the second MAC sub-entity are capable of uplink data processing.
10. The system of claim 9, wherein the MAC header further comprises a data identifier that determines one of a terminal transmitting the plurality of MAC service data units, a terminal group transmitting the plurality of MAC service data units, and a service related to the plurality of MAC service data units.
11. The system of claim 9, wherein the disassembling module is adapted to examine the channel identifier in the MAC header to identify whether the plurality of MAC service data units are being sent from at least one dedicated logical channel, and to map the plurality of MAC service data units to at least one dedicated logical channel.
12. The system of claim 9, wherein the disassembling module is adapted to examine the channel identifier in the MAC header to identify whether the plurality of MAC service data units are being sent from at least one common logical channel, and to map the plurality of MAC service data units to at least one common logical channel.
13. The system of claim 9, wherein the MAC header includes a type identifier to determine a type of the data identifier being transmitted.
14. The system of claim 9, wherein the MAC protocol data unit is received through the transport channel which is one of a random access channel and a dedicated channel in one TTI (Transmission Time Interval).

Patentansprüche

1. Terminal für eine Uplink-Verarbeitung in einem drahtlosen Kommunikationssystem, wobei das Terminal umfasst:
 - ein Empfangsmodul für das Empfangen von mehreren MAC (Medium Access Control)-Servicedateneinheiten;
 - ein Verknüpfungsmodul für das Verknüpfen der mehreren MAC-Servicedateneinheiten;
 - ein Header-Modul für das Zufügen eines MAC-Headers zu den mehreren verknüpften MAC-Servicedateneinheiten, um eine MAC-Protokolldateneinheit zu erzeugen, wobei der MAC-Header einen Kanalidentifizierer umfasst; und
 - ein Übertragungsmodul für das Übertragen der MAC-Protokolldateneinheit zu einer unteren Entität über einen

Transportkanal,

wobei die mehreren MAC-Servicedateneinheiten vom Empfangsmodul in einer MAC-Entität empfangen werden, die eine erste MAC-Unterentität und eine zweite MAC-Unterentität aufweist,

wobei der Kanalidentifizierer einen logischen Kanal identifiziert, der sich zwischen einer RLC (Radio Link Control)-Entität und der MAC-Entität befindet, und wobei sich der Transportkanal zwischen der MAC-Entität und der unteren Entität befindet,

wobei die mehreren verknüpften MAC-Servicedateneinheiten in der zweiten MAC-Unterentität gebildet werden, wobei die erste MAC-Unterentität eine MAC-d Unterentität für einen dedizierten Kanal ist und sich die zweite MAC-Unterentität unterhalb der MAC-d Unterentität befindet, und

wobei die erste MAC-Unterentität und die zweite MAC-Unterentität zur Uplink-Datenverarbeitung befähigt sind.

2. Terminal nach Anspruch 1, wobei die mehreren MAC-Servicedateneinheiten von wenigstens einem gemeinsamen logischen Kanal empfangen werden.

3. Terminal nach Anspruch 1, wobei die mehreren MAC-Servicedateneinheiten von wenigstens einem dedizierten logischen Kanal empfangen werden.

4. Terminal nach Anspruch 1, wobei der Kanalidentifizierer bestimmt, ob die mehreren MAC-Servicedateneinheiten von einem gemeinsamen logischen Kanal oder einem dedizierten logischen Kanal gesendet werden.

5. Terminal nach Anspruch 1, wobei der Kanalidentifizierer eine Art des logischen Kanals bestimmt.

6. Terminal nach Anspruch 1, wobei der MAC-Header weiter einen Datenidentifizierer umfasst, der wenigstens eines von einem Terminal, das die mehreren MAC-Servicedateneinheiten sendet, einer Gruppe von Terminals, die die mehreren MAC-Servicedateneinheiten senden, und einem auf die mehreren MAC-Servicedateneinheiten bezogenen Dienst bestimmt.

7. Terminal nach Anspruch 6, wobei das Header-Modul ausgelegt ist, um einen Typ-Identifizierer in den MAC-Header einzufügen, wobei der Typ-Identifizierer eine Art des übertragenen Datenidentifizierers angibt.

8. Terminal nach Anspruch 1, wobei die MAC-Protokolldateneinheit über einen Transportkanal übertragen wird, der entweder ein Zufallzugriffskanal (random access channel) oder ein dedizierter Kanal in einem TTI (Transmission Time Interval) ist.

9. System für eine Uplink-Verarbeitung in einem drahtlosen Kommunikationsnetzwerk, wobei das System umfasst:

- ein Empfangsmodul für das Empfangen einer MAC (Medium Access Control)-Protokolldateneinheit von einer unteren Entität über einen Transportkanal, wobei die MAC-Protokolldateneinheit einen MAC-Header und mehrere MAC-Servicedateneinheiten, die verknüpft sind, umfasst;

- ein Extraktionsmodul für das Extrahieren des MAC-Headers von der empfangenen MAC-Protokolldateneinheit, wobei der MAC-Header einen Kanalidentifizierer umfasst; und

- eine Zerlegungseinheit für das Zerlegen der mehreren MAC-Servicedateneinheiten und das Übertragen der individuellen MAC-Servicedateneinheiten zu einer RLC (Radio Link Control)-Entität,

wobei die MAC-Protokolldateneinheit vom Empfangsmodul in einer MAC-Entität des Systems empfangen wird, die eine erste MAC-Unterentität und eine zweite MAC-Unterentität aufweist,

wobei der Kanalidentifizierer einen logischen Kanal identifiziert, der sich zwischen der RLC-Entität und der MAC-Entität befindet, und wobei sich der Transportkanal zwischen der MAC-Entität und der unteren Entität befindet, und

wobei die mehreren MAC-Servicedateneinheiten in der zweiten MAC-Unterentität zerlegt werden, wobei die erste MAC-Unterentität eine MAC-d Unterentität für einen dedizierten Kanal ist und sich die zweite MAC-Unterentität unterhalb der MAC-d Unterentität befindet, und

wobei die erste MAC-Unterentität und die zweite MAC-Unterentität zur Uplink-Datenverarbeitung befähigt sind.

10. System nach Anspruch 9, wobei der MAC-Header weiter einen Datenidentifizierer umfasst, der wenigstens eines von einem Terminal, das die mehreren MAC-Servicedateneinheiten sendet, einer Gruppe von Terminals, die die mehreren MAC-Servicedateneinheiten senden, und einem auf die mehreren MAC-Servicedateneinheiten bezogenen Dienst bestimmt.

11. System nach Anspruch 9, wobei das Zerlegungsmodul eingerichtet ist, um den Kanalidentifizierer im MAC-Header zu überprüfen, um zu identifizieren, ob die mehreren MAC-Servicedateneinheiten von wenigstens einem dedizierten logischen Kanal gesendet werden, und um die mehreren MAC-Servicedateneinheiten auf wenigstens einen dedizierten logischen Kanal abzubilden.
12. System nach Anspruch 9, wobei das Zerlegungsmodul eingerichtet ist, um den Kanalidentifizierer im MAC-Header zu überprüfen, um zu identifizieren, ob die mehreren MAC-Servicedateneinheiten von wenigstens einem gemeinsamen logischen Kanal gesendet werden, und um die mehreren MAC-Servicedateneinheiten auf wenigstens einen gemeinsamen logischen Kanal abzubilden.
13. System nach Anspruch 9, wobei der MAC-Header einen Typ-Identifizierer umfasst, um eine Art des übertragenen Datenidentifizierers zu bestimmen.
14. System nach Anspruch 9, wobei die MAC-Protokolldateneinheit über einen Transportkanal empfangen wird, der entweder ein Zufallzugriffskanal (random access channel) oder ein dedizierter Kanal in einem TTI (Transmission Time Interval) ist.

Revendications

1. Terminal pour traitement de liaison montante dans un système de communication sans fil, le terminal comprenant:
 - un module de réception pour recevoir une pluralité d'unités de données de service MAC (commande d'accès au support);
 - un module de concaténation pour concaténer la pluralité d'unités de données de service MAC;
 - un module d'en-tête pour ajouter un en-tête MAC à la pluralité d'unités de données de service MAC concaténées afin de produire une unité de données de protocole MAC, l'en-tête MAC comprenant un identifiant de canal; et
 - un module d'envoi pour envoyer l'unité de données de protocole MAC à une entité inférieure par l'intermédiaire d'un canal de transport,
 - dans lequel la pluralité d'unités de données de service MAC sont reçues par le module de réception dans une entité MAC comportant une première sous-entité MAC et une seconde sous-entité MAC,
 - dans lequel l'identifiant de canal identifie un canal logique qui est établi entre une entité RLC (commande de liaison radio) et l'entité MAC, et le canal de transport est établi entre l'entité MAC et l'entité inférieure,
 - dans lequel la pluralité d'unités de données de service MAC concaténées sont formées dans la seconde sous-entité MAC,
 - dans lequel la première sous-entité MAC est une sous-entité MAC-d pour un canal dédié et la seconde sous-entité MAC se trouve au-dessous de la sous-entité MAC-d, et
 - dans lequel la première sous-entité MAC et la seconde sous-entité MAC sont capables d'effectuer un traitement de données de liaison montante.
2. Terminal selon la revendication 1, dans lequel la pluralité d'unités de données de service MAC sont reçues en provenance d'au moins un canal logique commun.
3. Terminal selon la revendication 1, dans lequel la pluralité d'unités de données de service MAC sont reçues en provenance d'au moins un canal logique dédié.
4. Terminal selon la revendication 1, dans lequel l'identifiant de canal détermine si la pluralité d'unités de données de service MAC sont envoyées en provenance d'un canal logique commun ou d'un canal logique dédié.
5. Terminal selon la revendication 1, dans lequel l'identifiant de canal détermine un type du canal logique.
6. Terminal selon la revendication 1, dans lequel l'en-tête MAC comprend en outre un identifiant de données qui détermine soit un terminal envoyant la pluralité d'unités de données de service MAC, soit un groupe de terminaux envoyant la pluralité d'unités de données de service MAC, soit un service relatif à la pluralité d'unités de données de service MAC.
7. Terminal selon la revendication 6, dans lequel le module d'en-tête est configuré pour inclure un identifiant de type dans l'en-tête MAC, l'identifiant de type indiquant un type de l'identifiant de données qui est envoyé.

8. Terminal selon la revendication 1, dans lequel l'unité de données de protocole MAC est transmise par le canal de transport qui est soit un canal d'accès aléatoire soit un canal dédié dans un seul TTI (intervalle de temps de transmission).

9. Système de traitement de liaison montante dans un réseau de communication sans fil, le système comprenant:

un module de réception pour recevoir une unité de données de protocole MAC (commande d'accès au support) provenant d'une entité inférieure par l'intermédiaire d'un canal de transport, l'unité de données de protocole MAC comprenant un en-tête MAC et une pluralité d'unités de données de service MAC qui sont concaténées;
un module d'extraction pour extraire l'en-tête MAC de l'unité de données de protocole MAC reçue, l'en-tête MAC comprenant un identifiant de canal; et
une unité de désassemblage pour désassembler la pluralité d'unités de données de service MAC et envoyer les unités de données de service MAC individuelles à une entité RLC (commande de liaison radio), dans lequel l'unité de données de protocole MAC est reçue par le module de réception dans une entité MAC du système comportant une première sous-unité MAC et une seconde sous-unité MAC, dans lequel l'identifiant de canal identifie un canal logique qui est établi entre l'entité RLC et l'entité MAC, et le canal de transport est établi entre l'entité MAC et l'entité inférieure, et dans lequel la pluralité d'unités de données de service MAC sont désassemblées dans la seconde sous-entité MAC, dans lequel la première sous-entité MAC est une sous-entité MAC-d pour un canal dédié et la seconde sous-entité MAC se trouve au-dessous de la sous-entité MAC-d, et dans lequel la première sous-entité MAC et la seconde sous-entité MAC sont capables d'effectuer un traitement de données de liaison montante.

10. Système selon la revendication 9, dans lequel l'en-tête MAC comprend en outre un identifiant de données qui détermine soit un terminal envoyant la pluralité d'unités de données de service MAC, soit un groupe de terminaux envoyant la pluralité d'unités de données de service MAC, soit un service relatif à la pluralité d'unités de données de service MAC.

11. Système selon la revendication 9, dans lequel le module de désassemblage est conçu pour examiner l'identifiant de canal figurant dans l'en-tête MAC afin d'identifier si la pluralité d'unités de données de service MAC sont envoyées en provenance d'au moins un canal logique dédié, et pour mapper la pluralité d'unités de données de service MAC à au moins un canal logique dédié.

12. Système selon la revendication 9, dans lequel le module de désassemblage est conçu pour examiner l'identifiant de canal figurant dans l'en-tête MAC afin d'identifier si la pluralité d'unités de données de service MAC sont envoyées en provenance d'au moins un canal logique commun, et pour mapper la pluralité d'unités de données de service MAC à au moins un canal logique commun.

13. Système selon la revendication 9, dans lequel l'en-tête MAC comprend un identifiant de type qui détermine un type de l'identifiant de données qui est envoyé.

14. Système selon la revendication 9, dans lequel l'unité de données de protocole MAC est reçue par l'intermédiaire du canal de transport qui est soit un canal d'accès aléatoire soit un canal dédié dans un seul TTI (intervalle de temps de transmission).
