Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

EP 2 468 519 B9

Description

Technical Field

[0001] The present invention relates to a tape cassette that can removably be installed in a tape printer.

Background Art

[0002] Conventionally, when a box-shaped tape cassette is installed in a cassette housing portion of a tape printer, the tape cassette is vertically inserted such that the plane surfaces (that is, the top and bottom surfaces) of the tape cassette match the upwardly-opening cassette housing portion. More specifically, when a user vertically installs the box-shaped tape cassette having side surfaces with a certain height in the cassette housing portion, the user sandwiches the side surfaces with his or her fingers and maintains the plane surfaces substantially horizontal.

Citation List

Patent Literature

[0003] PTL 1: Japanese Patent 3543659

[0004] The US 5,771,803 discloses a tape cassette including a thermal stencil paper thermally perforatable by a thermal print head of the tape printer; and a stencil sheet case housing the thermal stencil paper and having a portion shaped the same as a mountable portion of a print tape case housing a print tape. The cassette also includes an indicator for indicating when thermal stencil paper is housed in the cassette.

[0005] The US 2006/233582 A1 discloses a tape cassette which has logos including characters and symbols, formed in a position facing to feed paths of tapes and an ink ribbon in an outer wall face of the cassette case. The tape cassette is provided with the logos formed in a recessed shape in the position facing to the feed guidance in a logo formed part of the outer wall face of the lower case, and the protrusive part formed in the inner wall face of the lower case as the logos are formed and providing a feeding restriction part of restricting movement of the printing tape and the ink ribbon in the respective width.

Summary of Invention

[0006] However, it may be difficult for the user to maintain the plane surfaces substantially horizontal at the installation of the tape cassette, due to the arrangement positions of a tape and an ink ribbon housed inside the tape cassette. In such a case, the tape cassette may be inserted in the cassette housing portion in an inclined state. If printing is performed while the inclined tape cassette is installed in the tape printer, a feeding failure of the tape or ink ribbon, or a printing failure of a print head may occur.

[0007] An object of the present invention is to provide a tape cassette that can be accurately and smoothly installed in and removed from a tape printer. It is another object of the present invention to provide a tape printer in which a tape cassette can be accurately and smoothly installed and from which the tape cassette can be accurately and smoothly removed.

[0008] A tape cassette according to the present invention is set out in claim 1, preferred embodiments are defined in the dependent claims.

[0009] The tape cassette includes the pair of cavities at opposite ends of the diagonal connecting the first corner portion and the second corner portion of the generally rectangular box-like housing. Therefore, in a case where the tape cassette is installed in or removed from a tape printer that has at least one guide shaft that can be inserted in at least one of the cavities, the tape cassette can be accurately and smoothly installed or removed while being guided along the at least one guide shaft. If the tape printer has two guide shafts, the tape cassette can be more accurately and smoothly installed or removed.

[0010] The tape cassette can be stably guided in an installation/removal direction at two points between which a distance is the largest in the tape cassette in a plan view.

[0011] The tape cassette may further include a tape feed roller that has a cylindrical shape, that is rotatably disposed between the top wall and the bottom wall adapted to draw out the at least one tape, and that has an insert hole opening in the bottom wall via one of the pair of cavities.

[0012] In such a case, a guidet shaft of a tape printer can be inserted in the insert hole of the tape feed roller via one of the pair of cavities. Therefore, the tape cassette can be accurately and smoothly installed or removed along the guide shaft through the insert hole.

[0013] A roller support shaft adapted to rotatably support the tape feed roller may be fitted in the insert hole of the tape feed roller via the one of the pair of cavities of the tape cassette.

[0014] In such a case, a guide shaft to be inserted in one of the pair of cavities may be the roller support shaft that rotates the tape feed roller. Thus, the tape feed roller or its vicinity, which has a large influence on the print quality and tape feeding, may be accurately guided and positioned by the roller support shaft. Moreover, an additional shaft to be inserted in one of the pair of cavities may not be needed separately from the roller support shaft. Therefore, the configuration of the tape printer may be simplified.

[0015] The tape cassette may further include an ink ribbon wound and mounted within the housing to be used for printing on a print medium tape, which is one of the at least one tape. A center of gravity of one of the at least one tape may be located in a first area, which is one of two areas formed by dividing the housing with respect to a line connecting the pair of cavities. On the other hand,

a center of gravity of the ink ribbon may be located in a second area, which is one of the two areas other than the first area.

[0016] In such a case, since the tape and the ink ribbon, which are both heavy members in the tape cassette, are separately disposed in different areas, a weight difference between the first area and the second area may be reduced to restrict a weight imbalance in the tape cassette. As a result, an inclination due to the own weight of the tape cassette may be prevented when the tape cassette is installed in the tape printer. Therefore, the tape cassette may be further accurately and smoothly guided to the proper position along the at least guide shaft.

[0017] The tape cassette may further include a ribbon take-up spool rotatably disposed within the housing to draw out and take up the ink ribbon, and a center of gravity of the ribbon take-up spool may be located in the second area.

[0018] In such a case, even if the tape in the first area is heavier than the ink ribbon in the second area, the weight difference between the first area and the second area may be reduced due to the weight of the ribbon take-up spool. Therefore, the weight imbalance in the tape cassette may be restricted.

[0019] In case at least one of the pair of cavities is formed as a through-hole that extends through the top wall and the bottom wall at respective positions opposing each other in a vertical direction of the housing, at least one of the pair of cavities may be easily formed. Moreover, regardless of the length of the at least one guide shaft to be inserted in the at least one of the pair of cavities, the tape cassette may be smoothly guided by the at least one guide shaft.

[0020] In the tape cassette the cavities extend upwards from the bottom wall.

[0021] A movement of a guide shaft to be inserted in the second cavity is restricted in a circumferential direction by an internal wall of the second cavity. Therefore, the tape cassette is accurately and smoothly guided by at least one guide shaft. In an example not covered by the claims, the upper end of the guide shaft may contact a ceiling end of the indentation to restrict a movement of the tape cassette in the downward direction. In other words, the guide shaft may be used to position the tape cassette in the vertical direction. Therefore, additional member for positioning the tape cassette in the vertical direction may not be needed separately from the guide shaft. Therefore, the configuration of the tape printer may be simplified.

[0022] In the tape cassette according to the first aspect, one of the cavities may extend from an elongated opening.

[0023] In such a case, in a case where a cylindrically shaped guide shaft is inserted in one of the cavities, looseness can be allowed in a longitudinal direction of the elongated opening. Therefore, a load of a user in positioning the tape cassette may be reduced.

[0024] The elongated opening may have a width to al-

low at least a part of a side portion of a guide shaft, which is adapted to guide the tape cassette when the tape cassette is installed in or removed from a tape printer, to be tightly engaged when the guide shaft is inserted therein.

[0025] In such a case, when the tape cassette is installed, the tape cassette may be positioned in a direction in which the one of the pair of cavities is tightly engaged with the guide shaft.

[0026] A printing device, which is not claimed, is adapted to perform printing on a print medium tape of the at least one tape fed by the tape feeding device at a print position on the predetermined feed path. Two guide shafts might be adapted to be inserted in the pair of cavities and guide the tape cassette when the tape cassette is installed in or removed from the cassette housing portion in the installation/removal direction. The two guide shafts includes a first guide shaft disposed at a first position that opposes the first cavity when the tape cassette is installed in the cassette housing portion, and a second guide shaft disposed at a second position that opposes the second cavity when the tape cassette is installed in the cassette housing portion.

[0027] The tape printer includes two guide shafts adapted to guide the tape cassette that is installed in or removed from the cassette housing portion in the installation/removal direction. The two guide shafts are disposed at positions that correspond to the pair of cavities provided at two diagonal positions of the tape cassette, that is, two positions between which a distance is the largest in the tape cassette installed in the cassette housing portion. Therefore, the tape cassette may be stably guided in the installation/removal direction along the two guide shafts.

[0028] The tape cassette may include a tape feed roller that has a cylindrical shape, that is rotatably disposed between the top wall and the bottom wall, and that has an insert hole that opens in the bottom wall via the first cavity. In addition, a first guide shaft may be adapted to be inserted in the tape feed roller via the first cavity to rotatably support the tape feed roller and transmit a rotational drive force caused by the tape feeding device to the tape feed roller, thereby causing the tape feed roller to draw out the at least one tape.

[0029] In such a case, the first guide shaft may serve as a roller support shaft that rotates the tape feed roller to draw out the at least one tape. The roller support shaft may be inserted in the insert hole of the tape feed roller via the first cavity provided in the tape cassette. Thus, the tape feed roller or its vicinity, which has a large influence on the print quality and tape feeding, may be accurately guided and positioned by the roller support shaft. Moreover, an additional shaft to be inserted in the first cavity may not be needed separately from the roller support shaft. Therefore, the configuration of the tape printer may be simplified.

[0030] The tape printer may further include a head holder that holds a print head as the printing device. The tape cassette may include a head insertion portion into

which the head holder is inserted and within which the print head is held when the tape cassette is installed in the cassette housing portion, the head insertion portion being a space extending through the housing in a vertical direction. When the tape cassette is installed in the cassette housing portion, the first guide shaft and the second guide shaft may be respectively inserted in the first cavity and the second cavity before the print head held by the head holder is inserted in the head insertion portion.

[0031] In such a case, the print head may be smoothly inserted in the head insertion portion in a state that the tape cassette is stably guided along the two guide shafts. Moreover, the print head may be accurately positioned within the head insertion portion. Therefore, the print quality with the print head may be improved.

[0032] In the tape printer, the tape cassette may include an ink ribbon wound and mounted within the housing to be used for printing on the print medium tape, and a ribbon take-up spool rotatably disposed within the housing to draw out and take up the ink ribbon. In addition, the tape printer may further include a ribbon take-up shaft adapted to be fitted in the ribbon take-up spool and rotate the ribbon take-up spool around an axis of the ribbon take-up shaft, thereby causing the ribbon take-up spool to draw out and take up the ink ribbon. When the tape cassette is installed in the cassette housing portion, the first guide shaft and the second guide shaft may be respectively inserted in the first cavity and the second cavity before the ribbon take-up shaft is fitted in the ribbon take-up spool.

[0033] In such a case, the ribbon take-up shaft may be smoothly fitted in the ribbon take-up spool in a state that the tape cassette is stably guided along the two guide shafts. Moreover, since the ribbon take-up shaft is accurately fitted in the ribbon take-up spool, a ribbon feeding accuracy of the ribbon take-up spool may be improved.

[0034] In the tape printer, the second cavity may extend from an elongated opening that has a width to allow at least a part of a side portion of the second guide shaft to be tightly engaged when the second guide shaft is inserted therein. When the tape cassette is installed at a proper position in the cassette housing portion, the second guide shaft inserted in the second cavity may engage with the second cavity.

[0035] In such a case, the second guide shaft may not only guide the tape cassette in the installation/removal direction, but also position the tape cassette at the proper position by engaging with the second cavity.

[0036] In the tape printer according to the second aspect, the cassette housing portion may have a rectangular opening that corresponds to a plan shape of the box-like housing. The first guide shaft may be disposed in the vicinity of or at a first corner portion of the rectangular opening, the first corner portion of the rectangular opening being one of the corner portions of the rectangular opening and being positioned at a downstream side of the print position in a feed direction of the print medium tape. The second guide shaft may be disposed in the

vicinity of or at a second corner portion of the rectangular opening, the second corner portion of the rectangular opening being another corner portion of the rectangular opening and being positioned diagonal to the first corner portion of the rectangular opening.

[0037] In such a case, the tape cassette may be installed in or removed via the rectangular opening along the two guide shaft provided at diagonal positions of the rectangular cassette housing portion.

Brief Description of Drawings

[0038]

FIG. 1 is a perspective view of a tape printer 1 according to a first embodiment in a state where a cassette cover 6 is closed.

FIG. 2 is a perspective view of the tape printer 1 in a state where the cassette cover 6 is opened according to the first embodiment.

FIG. 3 is a perspective view illustrating a tape cassette 30 and a cassette housing portion 8 according to the first embodiment.

FIG. 4 is a plan view of the cassette housing portion 8 according to the first embodiment.

FIG. 5 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed, when a platen holder 12 is at a standby position.

FIG. 6 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed, when the platen holder 12 is at a print position.

FIG. 7 is a side sectional view illustrating a state in which the tape cassette 30 and the platen holder 12 are oppositely arranged.

FIG. 8 is a plan view of the tape cassette 30.

FIG. 9 is a bottom view of the tape cassette 30.

FIG. 10 is a front sectional view of the tape cassette 30 about a first tape support hole 65 and a first tape spool 40.

FIG. 11 is a front sectional view of the tape cassette 30 about a take-up spool support hole 67 and a ribbon take-up spool 44.

FIG. 12 is an enlarged and exploded perspective view of a roller support hole 64 and a tape feed roller 46.

FIG. 13 is a side sectional view of the tape cassette 30 about a guide hole 47.

FIG. 14 is a right side view showing an installation process of the tape cassette 30 in the cassette housing portion 8 according to the first embodiment.

FIG. 15 is another right side view of the installation process of the tape cassette 30 in the cassette housing portion 8 according to the first embodiment.

FIG. 16 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the first embodiment.

FIG. 17 is a front sectional view showing a state in which a tape drive shaft 100 is inserted in the tape feed roller 46.

FIG. 18 is a front sectional view showing a state in which a ribbon take-up shaft 95 is inserted in the ribbon take-up spool 44.

FIG. 19 is a plan view of the cassette housing portion 8 according to a variant of the first embodiment.

[fig.20]FIG. 20 is a plan view of the tape cassette 30 according to the variant of the first embodiment.

[fig.21]FIG. 21 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed.

FIG. 22 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the variant of the first embodiment.

FIG. 23 is a plan view enlarged about the first tape support hole 65 of the cassette housing portion 8 in which a tape cassette 30 is installed.

FIG. 24 is a perspective view illustrating the tape cassette 30 and the cassette housing portion 8 according to a second embodiment.

FIG. 25 is a plan view of the cassette housing portion 8 according to the second embodiment.

FIG. 26 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed.

FIG. 27 is a right side view showing an installation process of the tape cassette 30 in the cassette housing portion 8 according to the second embodiment.

FIG. 28 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the second embodiment.

FIG. 29 is a plan view of the cassette housing portion 8 according to a variant of the second embodiment.

FIG. 30 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed.

FIG. 31 is a plan view of the cassette housing portion 8 in which a tape cassette 30, which is not covered by the claims, is installed.

FIG. 32 is a plan view of the cassette housing portion 8 in which the tape cassette 30 is installed according to a third embodiment.

FIG. 33 is a plan view of the tape cassette 30 according to a variant of the third embodiment.

FIG. 34 is a plan view of the cassette housing portion 8 in which the tape cassette 30 is installed according to the variant of the third embodiment.

FIG. 35 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the variant of the third embodiment.

FIG. 36 is a plan view of the cassette housing portion 8 in which the tape cassette 30 is installed according to a fourth embodiment.

FIG. 37 is a right side view showing a state in which

the tape cassette 30 is installed in the cassette housing portion 8 according to the fourth embodiment.

FIG. 38 is a perspective view illustrating the tape cassette 30 and the cassette housing portion 8 according to a first modified embodiment.

FIG. 39 is a plan view of the cassette housing portion 8 according to the first modified embodiment.

FIG. 40 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the first modified embodiment.

FIG. 41 is a right side view showing a state in which the tape cassette 30 is installed in the cassette housing portion 8 according to the first modified embodiment.

FIG. 42 is a perspective view illustrating the tape cassette 30, which is not covered by the claims, and the cassette housing portion 8 according to a second modified embodiment.

FIG. 43 is a right side view showing a state in which the tape cassette 30, which is not covered by the claims, is installed in the cassette housing portion 8 according to the second modified embodiment.

FIG. 44 is a perspective view illustrating a tape cassette 30 and a cassette housing portion 8 according to a third modified embodiment.

FIG. 45 is a plan view of the cassette housing portion 8 in which the tape cassette 30 is installed according to a fourth modified embodiment.

FIG. 46 is a plan view of the tape cassette 30 showing a modified embodiment of a guide hole 47.

FIG. 47 is a plan view of the tape cassette 30 showing another modified embodiment of the guide hole 47.

FIG. 48 is a plan view of the tape cassette 30 showing yet another modified embodiment of the guide hole 47.

FIG. 49 is a perspective view in which the right side of the tape cassette 30 is enlarged showing yet another modified embodiment of the guide hole 47.

FIG. 50 is a right side view showing a state in which the tape cassette 30 shown in FIG. 49 is installed in the cassette housing portion 8.

FIG. 51 is a plan view of the tape cassette 30 showing yet another modified embodiment of the guide hole 47.

FIG. 52 is a plan view of the tape cassette 30 showing yet another modified embodiment of the guide hole 47.

FIG. 53 is a plan view of the tape cassette 30 showing yet another modified embodiment of the guide hole 47.

FIG. 54 is a perspective view in which the right side of the tape cassette 30, which is not covered by the claims, is enlarged showing yet another modified embodiment of the guide hole 47.

FIG. 55 is a right side view showing a state in which the tape cassette 30, which is not covered by the claims, shown in FIG. 54 is installed in the cassette

housing portion 8.

FIG. 56 is a front sectional view of the tape cassette 30 about the first tape support hole 65 and the first tape spool 40 according to a modified embodiment.

FIG. 57 is a right side view exemplifying a state in which the tape cassette 30 is exhibited.

Description of Embodiments

[0039] Exemplary embodiments embodying the present invention will be described below with reference to the drawings. The configurations of the apparatuses, the flowcharts of various processing and the like described below and shown in the drawings are merely exemplary and do not intend to limit the present invention.

[0040] In the following explanation, the upper side, the lower side, the lower left side, the upper right side, the lower right side and the upper left side in FIG. 1 are respectively defined as the upper side, the lower side, the front side, the rear side, the right side and the left side of a tape printer 1. In addition, the upper side, the lower side, the lower right side, the upper left side, the upper light side and the lower left side in FIG. 3 are respectively defined as the upper side, the lower side, the front side, the rear side, the right side and the left side of a tape cassette 30 (similar also in FIGS. 24, 38, 42 and 44).

[0041] In actuality, a group of gears, including gears 91, 93, 94, 97, 98 and 101 shown in FIG. 3, is covered and hidden by the bottom surface of a cavity 8A. However, the bottom surface of the cavity 8A is not shown in FIG. 3 for explaining the group of gears (similar also in FIGS. 24, 38, 42 and 44). Furthermore, FIG. 3 shows side walls that form a periphery around a cassette housing portion 8, but this is simply a schematic diagram, and the side walls shown in FIG. 3 are depicted as thicker than they are in actuality (similar also in FIG. 24). On the other hand, in FIG. 38, for ease of understanding, the cassette housing portion 8 is shown with the side walls that form the periphery thereof removed (similar also in FIGS. 42 and 44). Moreover, FIGS. 5 and 6 show the states in which the tape cassette 30 is installed in the cassette housing portion 8 with a top case 31A removed (similar also in FIGS. 21, 26, 30, 31, 32, 34, 36 and 45).

<First embodiment; the tape cassette of Fig. 5, 6, 21 is not covered by the claims,>

[0042] A tape printer 1 and a tape cassette 30 according to a first embodiment will be explained below with reference to FIGS. 1 to 23. The first embodiment describes an example in which the tape cassette 30 houses a tape (specifically, a heat-sensitive paper tape that is a print medium) therein, and has three guide holes for guiding the tape cassette 30 when the tape cassette 30 is installed in or removed from the tape printer 1. The first embodiment also describes an example in which the tape printer 1 has three guide shafts for guiding the tape cassette 30 to a proper installation position (hereinafter re-

ferred to as a proper position) corresponding to the three guide holes described above.

[0043] First, an outline configuration of the tape printer 1 according to the first embodiment will be explained. Hereinafter, the tape printer 1 configured as a general purpose device will be explained as an example. As the general purpose device, the tape printer 1 may commonly use a plurality of types of tape cassettes 30 with various types of tapes. The types of the tape cassettes 30 may include a thermal type tape cassette 30 that houses a heat-sensitive paper tape only, a receptor type tape cassette 30 that houses a print tape and an ink ribbon, and a laminated type tape cassette 30 that houses a double-sided adhesive tape, a film tape and an ink ribbon.

[0044] As shown in FIGS. 1 and 2, the tape printer 1 includes a main unit cover 2 that has a rectangular shape in a plan view. A keyboard 3 is provided on the front side of the main unit cover 2. The keyboard 3 includes character keys for characters (letters, symbols, numerals and so on), a variety of function keys, and so on. A liquid crystal display 5 is provided on the rear side of the keyboard 3. The liquid crystal display 5 displays input characters. A cassette cover 6 is provided on the rear side of the liquid crystal display 5. The cassette cover 6 may be opened and closed when the tape cassette 30 is replaced.

[0045] A discharge slit 9, from which the printed tape is discharged to the outside of the tape printer 1, is provided to the rear of the left side of the main unit cover 2. A discharge window 11 is formed on the left side face of the cassette cover 6 such that when the cassette cover 6 is in a closed state, the discharge slit 9 is exposed to the outside. Substantially at the center of the front face of the cassette cover 6, a hook-shaped latching lock 4, which projects downward from the lower surface of the cassette cover 6, is provided. The main unit cover 2 is provided with a lock hole 7 at a position corresponding to the latching lock 4, and the latching lock 4 is fitted and engaged with the lock hole 7 when the cassette cover 6 is closed, thereby preventing unintentional release of the cassette cover 6.

[0046] Next, an internal configuration within the main unit cover 2 will be explained with an emphasis on the cassette housing portion 8 with reference to FIGS. 2 to 7. FIGS. 3 to 6 schematically show the internal configuration within the main unit cover 2 (particularly, the shape, configuration and the like of the cassette housing portion 8) for ease of understanding. As shown in FIG. 3, the cassette housing portion 8 is provided in the interior of the main unit cover 2 below the cassette cover 6. The cassette housing portion 8 is an area which the tape cassette 30 can be installed in or removed from. The cassette housing portion 8 is equipped with a feed mechanism, a print mechanism, and the like.

[0047] As shown in FIGS. 2 to 7, a head holder 74 is fixed on the front portion of the cassette housing portion 8. A thermal head 10 including a heating element (not shown in the figures) is mounted on the head holder 74.

A tape feed motor 23 that is a stepping motor is provided outside the cassette housing portion 8 (the upper right side in FIG. 3). A drive gear 91 is anchored to the lower end of a drive shaft of the tape feed motor 23. The drive gear 91 is meshed with a gear 93 through an opening, and the gear 93 is meshed with a gear 94. A ribbon take-up shaft 95 is standing upward on the upper surface of the gear 94. The ribbon take-up shaft 95 has a substantially cylindrical shape, and drives to rotate a ribbon take-up spool 44, which will be described later. The ribbon take-up shaft 95 is provided with a plurality of cam members 95A extending from the base end of the shaft toward the leading end at the outer periphery to be radial in a plan view (refer to FIG. 14).

[0048] In addition, the gear 94 is meshed with a gear 97, the gear 97 is meshed with a gear 98, and the gear 98 is meshed with a gear 101. A tape drive shaft 100 is standing upward on the upper surface of the gear 101. The tape drive shaft 100 has a substantially cylindrical shape, and drives to rotate a tape feed roller 46, which will be described later. The tape drive shaft 100 is provided with a plurality of cam members 100A extending from the base end of the shaft toward the leading end at the outer periphery to be radial in a plan view (refer to FIG. 14). An auxiliary shaft 110 is standing upward at the rear side of the gear 98. The auxiliary shaft 110 has a substantially cylindrical shape, and can be inserted in and removed from a first tape support hole 65, which will be described later.

[0049] If the tape feed motor 23 is driven to rotate in the counterclockwise direction in a state where the tape cassette 30 is installed in the cassette housing portion 8, the ribbon take-up shaft 95 is driven to rotate in the counterclockwise direction via the drive gear 91, the gear 93 and the gear 94. The ribbon take-up shaft 95 causes the ribbon take-up spool 44, which is fitted with the ribbon take-up shaft 95, to rotate. Furthermore, the rotation of the gear 94 is transmitted to the tape drive shaft 100 via the gear 97, the gear 98 and the gear 101, to thereby drive the tape drive shaft 100 to rotate in the clockwise direction. The tape drive shaft 100 causes the tape feed roller 46, which is fitted with the tape drive shaft 100 by insertion, to rotate.

[0050] Two positioning pins 102 and 103 are provided at the periphery of the cassette housing portion 8. The positioning pin 102 is provided at the left edge portion of the cassette housing portion 8 corresponding to a pin hole 53 described later formed in the bottom surface of the tape cassette 30. The positioning pin 102 defines a height position (a position in the vertical direction) and a horizontal position (a position in the horizontal direction) of the tape cassette 30 at the left edge side of the tape cassette 30 installed in the cassette housing portion 8. The positioning pin 103 is provided at the right edge portion of the cassette housing portion 8 corresponding to a common portion 32 described later positioned at the rear right side of the tape cassette 30. The positioning pin 103 defines the height position of the tape cassette

30 at the right edge side of the tape cassette 30 installed in the cassette housing portion 8.

[0051] A guide shaft 120 is standing upward at the rear right side of the cassette housing portion 8. The guide shaft 120 can be inserted in and removed from a guide hole 47, which will be described later. The guide shaft 120 is a substantially cylindrical shaft that includes two shaft portions having different diameters (a large-diameter shaft portion 120A and a small-diameter shaft portion 120B) and a taper portion 120C connecting the large-diameter shaft portion 120A and the small-diameter shaft portion 120B (refer to FIG. 14). The large-diameter shaft portion 120A forms the base end side of the guide shaft 120 and has the largest diameter in the guide shaft 120. The small-diameter shaft portion 120B forms the leading end side of the guide shaft 120 and has a smaller diameter than the large-diameter shaft portion 120A. The taper portion 120C is provided between the large-diameter shaft portion 120A and the small-diameter shaft portion 120B, and has a taper-shaped inclined surface in which the diameter is gradually reduced from the large-diameter shaft portion 120A toward the small-diameter shaft portion 120B.

[0052] The cassette housing portion 8 has an opening with a substantially rectangular shape in a plan view that substantially corresponds to the plan shape of a cassette case 31. The cassette housing portion 8 includes a cavity 8A and a cassette support portion 8B. The cavity 8A is formed as a depression that has a generally rectangular shape with rounded corners in a plan view that corresponds to the shape of a bottom surface of a cassette case 31. The cassette support portion 8B is a flat portion extending horizontally from the outer edge of the cavity 8A. The cassette support portion 8B opposes the lower surface of the common portion 32 of the tape cassette 30 installed in the cassette housing portion 8 (described later in detail).

[0053] As shown in FIG. 7, a switch portion 20 is provided on the rear side surface of the platen holder 12 (that is, the surface opposite to the thermal head 10). The switch portion 20 includes a plurality of through-holes formed in the rear side surface of the platen holder 12, a sensor substrate 22, and a plurality of detecting switches 21 that respectively correspond to the through holes. One end of each of the detecting switches 21 is connected to the sensor substrate 22. Terminal shafts of the detecting switches 21 project rearward from the respective through-holes. The detecting switches 21 are selectively pressed by an arm indicator portion 80 of the tape cassette 30 to thereby detect a type of the tape cassette 30 installed in the cassette housing portion 8.

[0054] The positional relationships among the respective members standing upward in the cassette housing portion 8 will be explained with reference to FIG. 4. The two-dot chain line in FIG. 4 indicates a division line J described later. The tape drive shaft 100, the guide shaft 120, the auxiliary shaft 110, the ribbon take-up shaft 95, the positioning pin 102 and the head holder 74, which

are described above, are provided at positions that oppose the roller support hole 64, the guide hole 47, the first tape support hole 65, the take-up spool support hole 67, the pin hole 53 and the head insertion portion 39 (all of which are described later) provided in the tape cassette 30 when the tape cassette 30 is installed in the cassette housing portion 8, respectively.

[0055] The tape drive shaft 100 is standing upward in a first shaft installation area 8C including a corner portion positioned on the front left side of the cassette housing portion 8. More specifically, nine areas can be formed if the cassette housing portion 8, which is substantially rectangular in a plan view, is divided into three parts in its front-rear direction and left-right direction, respectively. The first shaft installation area 8C is an area at the foremost and leftmost position among the nine areas. The first shaft installation area 8C is adjacent to the left side of the head holder 74 fixed on the center of the front portion of the cassette housing portion 8 and is positioned on the downstream side of the print position of the thermal head 10 in a tape feed direction described later.

[0056] The guide shaft 120 is standing upward in a second shaft installation area 8D including a corner portion positioned on the rear right side of the cassette housing portion 8. More specifically, the second shaft installation area 8D is an area at the rearmost and rightmost position among the nine areas described above. In other words, when the cassette housing portion 8 is seen in a plan view, the corner portion included in the second shaft installation area 8D is at a diagonal position with respect to the corner portion included in the first shaft installation area 8C.

[0057] When the cassette housing portion 8 is divided in a plan view with reference to the division line J connecting the tape drive shaft 100 and the guide shaft 120, two areas are formed. An area that occupies the part at the rear side of the division line J is a first installation area 8E. The other area that occupies the part at the front side of the division line J is a second installation area 8F. The auxiliary shaft 110 is standing upward in the first installation area 8E. More specifically, the auxiliary shaft 110 is positioned at the rear left side of the center of the cassette housing portion 8 in a plan view. The ribbon take-up shaft 95 is standing upward in the second installation area 8F. More specifically, the ribbon take-up shaft 95 is positioned at the front right side of the center of the cassette housing portion 8 in a plan view. The auxiliary shaft 110 and the ribbon take-up shaft 95 are positioned substantially symmetrically across the division line J in a plan view.

[0058] The positioning pin 102 is adjacently provided at the rear side of the tape drive shaft 100. The positioning pin 103 is adjacently provided at the front side of the guide shaft 120. The positioning pins 102 and 103 support the tape cassette 30 installed in the cassette housing portion 8 in the vicinity of the tape drive shaft 100 and the guide shaft 120, respectively.

[0059] The positional relationships in a plan view

among the members standing upward in the cassette housing portion 8 are as described above. The height position from which each member is standing upward is different depending on whether it is standing from the cavity 8A or from the cassette support portion 8B. In other words, the members provided in the cassette support portion 8B (the guide shaft 120 and the positioning pins 102, 103) are standing upward from higher positions than the members provided in the cavity 8A (the ribbon take-up shaft 95, the tape drive shaft 100, the auxiliary shaft 110 and the head holder 74). The relationships in height among the members standing upward in the cassette housing portion 8 will be described later.

[0060] As shown in FIGS. 2 to 6, the arm-shaped platen holder 12 is pivotably supported around a support shaft 12A on the front side of the head holder 74. A platen roller 15 and a movable feed roller 14 are both rotatably supported on the leading end side of the platen holder 12. The platen roller 15 faces the thermal head 10 and may be moved close to and apart from the thermal head 10. The movable feed roller 14 faces the tape feed roller 46 that may be fitted with the tape drive shaft 100, and may be moved close to and apart from the tape feed roller 46.

[0061] A release lever (not shown in the figures), which moves in the left-right direction in response to the opening and closing of the cassette cover 6, is coupled to the platen holder 12. When the cassette cover 6 is opened, the release lever moves in the right direction, and the platen holder 12 moves toward a standby position shown in FIG. 5. The platen holder 12 has moved away from the cassette housing portion 8 at the standby position shown in FIG. 5, so that the tape cassette 30 can be installed in and removed from the cassette housing portion 8. The platen holder 12 is constantly elastically urged to remain at the standby position by a spiral spring (not shown in the figures).

[0062] When the cassette cover 6 is closed, the release lever moves in the left direction and the platen holder 12 moves toward a print position shown in FIG. 6. The platen holder 12 moves closer to the cassette housing portion 8 toward the print position shown in FIG. 6. Then, if the tape cassette 30 is installed in the cassette housing portion 8, the platen roller 15 presses the thermal head 10 via a tape which is a print medium (a heat-sensitive paper tape 55 in the present embodiment), and the movable feed roller 14 presses the tape feed roller 46 via the tape. Thus, at the print position shown in FIG. 6, printing can be performed using the tape cassette 30 installed in the cassette housing portion 8.

[0063] A feed path along which a printed tape is fed extends from a tape discharge aperture 49 to the discharge slit 9. A cutting mechanism 17 that cuts the printed tape at a predetermined position is provided on the feed path. The cutting mechanism 17 includes a fixed blade 18 and a movable blade 19 that opposes the fixed blade 18 and that is supported movably in the front-rear direction (in the vertical direction shown in FIGS. 5 and 6). The movable blade 19 is moved in the front-rear direction

by a cutter motor (not shown in the figures).

[0064] The configuration of the tape cassette 30 according to the first embodiment will be explained. Hereinafter, the tape cassette 30 configured as a general purpose cassette will be explained as an example. As the general purpose cassette, the tape cassette 30 may be assembled as the thermal type, the receptor type and the laminated type that have been explained above, by changing, as appropriate, the type of the tape to be mounted in the tape cassette 30 and by changing the presence or absence of the ink ribbon, and so on.

[0065] The general configuration of the tape cassette 30 will be explained with reference to FIGS. 3, 5 and 6 to 9. The tape cassette 30 includes a cassette case 31 that is a housing having a generally rectangular parallelepiped shape (box-like shape). The tape cassette 30 includes a bottom case 31B and a top case 31A fixed to an upper portion of the bottom case 31B. A rectangular planar portion of the top case 31A that is longer in left-right direction and that is perpendicular to an opposing direction of the top case 31A and the bottom case 31B is a top wall 35 of the cassette case 31. The planar portion of the bottom case 31B that has substantially the same shape as the top wall 35 and that is perpendicular to the opposing direction of the top case 31A and the bottom case 31B is a bottom wall 36 of the cassette case 31. A side portion of the top case 31A that extends downward from the outer edge of the top wall 35 toward the bottom case 31B and a side portion of the bottom case 31B that extends upward from the outer edge of the bottom wall 36 toward the top case 31A form a side wall 37 of the cassette case 31.

[0066] In other words, the cassette case 31 is a box-like housing that includes the top wall 35 and the bottom wall 36 which form rectangular planar portions oppositely arranged in the vertical direction, and the side wall 37 that is formed with a predetermined height over the outer edges of the top wall 35 and the bottom wall 36. In the cassette case 31, the entire peripheries of the top wall 35 and the bottom wall 36 may not have to be surrounded by the side wall 37 completely. A part of the side wall 37 (the rear wall, for example) may be provided with an opening that exposes the interior of the cassette case 31, or a boss that connects the top wall 35 and the bottom wall 36 may be provided at the opening. The vertical direction of the cassette case 31 (that is, the direction in which the top wall 35 and the bottom wall 36 oppose each other) substantially corresponds to a direction in which the tape cassette 30 is installed in and removed from the cassette housing portion 8 (that is, an installation/removal direction of the tape cassette 30).

[0067] The first tape support hole 65 is formed at the rear left side of the center of the tape cassette 30 in a plan view. The first tape support hole 65 rotatably supports the first tape spool 40 (refer to FIGS. 5 and 6) on which a first tape is wound. A second tape support hole 66 is formed at the rear right side of the center of the tape cassette 30 in a plan view. The second tape support hole

66 rotatably supports a second tape spool (not shown in the first embodiment) on which a second tape is wound. A ribbon support hole 68 is formed at the front right side of the center of the tape cassette 30 in a plan view. The ribbon support hole 68 rotatably supports a ribbon spool (not shown in the first embodiment) on which an ink ribbon is wound. The take-up spool support hole 67 is formed between the first tape support hole 65 and the ribbon support hole 68. The take-up spool support hole 67 rotatably supports the ribbon take-up spool 44. The ribbon take-up spool 44 pulls out an ink ribbon from the ribbon spool and takes up the ink ribbon that has been used for printing characters.

[0068] The tape cassette 30 according to an example not covered by the claims is assembled as a so-called thermal type tape cassette, in which the heat-sensitive paper tape 55 as a first tape is wound on the first tape spool 40. The thermal type tape cassette 30 does not include the second tape spool on which a second tape is wound, since another print medium does not need to be housed. Further, the thermal type tape cassette 30 does not include a ribbon spool on which an ink ribbon is wound, since no ink ribbon needs to be housed.

[0069] An arm portion 34 extends from the front right side of the tape cassette 30. The arm portion 34 is folded back at the right side at a right angle and extends toward the center of the tape cassette 30. The arm portion 34 guides an unused tape and an unused ink ribbon, and supplies them to the head insertion portion 39 from the exit 34A provided at the leading end thereof. The head insertion portion 39 is a space surrounded by an inner wall of the arm portion 34 and a wall opposing the inner wall and extending through the cassette case 31 in the vertical direction. As shown in FIGS. 5 and 6, the thermal head 10 of the tape printer 1 can be inserted in the head insertion portion 39. The head insertion portion 39 has an opening width wider than the thickness (the length in the front-rear direction) of the head holder 74 and the lateral width (the length in the left-right direction) such that when the head holder 74 having the thermal head 10 is inserted, looseness may be allowed for the head holder 74 in the front-rear direction and the left-right direction.

[0070] An arm side wall 33, which is a front wall of the arm portion 34, is provided with the arm indicator portion 80. The arm indicator portion 80 is formed in a specified pattern in accordance with a type of the tape cassette 30 (tape width, tape type, etc., for example). The arm indicator portion 80 includes indicators that respectively correspond to the arm detecting switches 21. Each of the indicators is either one of a non-pressing portion 81 and a pressing portion 82. The non-pressing portion 81 is a switch hole through which a switch terminal can be inserted or removed. The pressing portion 82 is a surface portion through which a switch terminal cannot be inserted.

[0071] The roller support hole 64 is provided at the front left portion of the tape cassette 30. The tape feed roller

46 is rotatably supported inside the roller support hole 64. The tape feed roller 46 pulls out an unused tape in concert with the corresponding movable feed roller 14. A pair of regulating members 63 that matches in the vertical direction is provided on the upstream side of the tape feed roller 46 in the tape feed direction. The regulating members 63 regulate the printed tape in a width direction of the tape on the downstream side of the thermal head 10 in the tape feed direction, and guide it toward the tape discharge aperture 49. The tape feed direction is a direction in which a tape mounted in the tape cassette 30 is fed within the cassette housing portion 8 when printing is performed in the tape printer 1.

[0072] As shown in FIGS. 5, 6, 8 and 9, the guide hole 47 according to the first embodiment has an opening shape such that both sides opposite to each other in the front-rear direction in a plan view are linear, and both sides opposing each other in the left-right direction are curved. A distance from the center of the opening of the guide hole 47 to any point on the curved sides is constant. The opening width of the guide hole 47 is larger than the diameter of the small-diameter shaft portion 120B of the guide shaft 120 in all directions through the center of the opening of the guide hole 47 in a plan view. In the guide hole 47, the opening width in the left-right direction through the center of the opening of the guide hole 47 in a plan view is the largest, and the opening width in the front-rear direction through the center of the opening of the guide hole 47 in a plan view is the smallest. The opening width in the front-rear direction through the center of the opening of the guide hole 47 is substantially equal to the diameter of the large-diameter shaft portion 120A of the guide shaft 120.

[0073] A guide wall 38 is standing upward in the vicinity of the regulating members 63. A separating wall 48 is standing upward between the guide wall 38 and the ribbon take-up spool 44. The above configurations fulfill their functions when the tape cassette 30 is of the laminated type (refer to FIG. 36). Specifically, the guide wall 38 separates a used ink ribbon fed via the head insertion portion 39 from a film tape, and guides the used ink ribbon toward the ribbon take-up spool 44. The separating wall 48 prevents mutual contact between the used ink ribbon guided along the guide wall 38 and the double-sided adhesive tape that is wound on and supported by the first tape spool 40.

[0074] As shown in FIG. 3, the cassette case 31 has a generally rectangular parallelepiped shape with rounded corner portions. The common portion 32 having a constant width (a height T described later) is provided along a predetermined height of all the sides of the cassette case 31 regardless of a type of the tape cassette 30 (the tape width, for example). The common portion 32 horizontally projects in the outward direction to form a right angle in a plan view at predetermined corner portions of the cassette case 31 (more specifically, corner portions at which the tape discharge aperture 49 is not provided).

[0075] The common portion 32 opposes the cassette

support portion 8B within the cassette housing portion 8 when the tape cassette 30 is installed in the cassette housing portion 8. At this time, in the cassette housing portion 8, the cassette case 31 is fitted in the cavity 8A up to a predetermined height position from the bottom surface of the cassette case 31 (that is, up to the lower surface of the common portion 32). Thus, the common portion 32 is held at a same height position by the cassette support portion 8B regardless of the thickness (the length in the vertical direction of the cassette case 31) of the tape cassette 30.

[0076] More specifically, as shown in FIG. 7, the common portion 32 has a height T formed to be symmetrical in the vertical direction with respect to a center line N in the height (width) direction of the cassette case 31 (also refer to FIG. 13). The height T of the common portion 32 is set to be constant regardless of the tape width of the print medium mounted in the cassette case 31. For example, when the height T of the common portion 32 is 12 mm, as the tape width becomes larger (18 mm, 24 mm, 36 mm, for example), the height of the cassette case 31 also becomes larger, but the height T of the common portion 32 remains constant. If the tape width is equal to or less than the height T (6 mm, 12 mm, for example), the height of the cassette case 31 is the width T of the common portion 32 (12mm) plus a predetermined width..

[0077] Some portions of the tape cassette 30 will be explained in detail with reference to FIGS. 10 to 13. A description will be given below of the holes formed in the tape cassette 30 (the first tape support hole 65, the take-up spool support hole 67, the roller support hole 64 and the guide hole 47) and the members associated with the holes.

[0078] As shown in FIG. 10, the first tape spool 40 is rotatably supported by the first tape support hole 65 extending through the cassette case 31 in the vertical direction. More specifically, the first tape support hole 65 includes an opening 65A and an opening 65B, and a shaft hole 65C that connects the openings 65A and 65B. Both the openings 65A and 65B are provided at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. The top case 31A has a pair of latching ribs 84. The latching ribs 84 extend downward from the opening 65A toward the bottom wall 36 and provided at opposite positions across the center of the opening 65A in a plan view. The latching ribs 84 each have a hook shape. The leading ends of the hooks project toward each other inside the cassette case 31.

[0079] The bottom case 31B includes a cylindrical wall portion 85 having a cylindrical shape which extends upward from the opening 65B toward the top wall 35. A pair of slits 87, which are cuts extending in the vertical direction, is provided in the cylindrical wall portion 85. The slits 87 are provided at opposite positions across the center of the opening 65B in a plan view. A head portion 86 that closes an opening end of each slit 87 is provided at the upper end side of each slit 87 in the cylindrical wall portion 85. The corresponding latching rib 84 is engaged with

each head portion 86 provided at the leading end of the cylindrical wall portion 85 via each slit 87 within the cassette case 31. The shaft hole 65C that extends through the cassette case 31 in the vertical direction connects the openings 65A and 65B inside the cylindrical wall portion 85.

[0080] The first tape spool 40 has a double-wall configuration with an internal wall 40A and an external wall 40B. The internal wall 40A is a cylindrical member, and has the inner diameter slightly larger than the outer diameter of the cylindrical wall portion 85. The internal wall 40A has a height that is smaller than the tape width of the print medium. A shaft hole 40D that extends through the internal wall 40A in the vertical direction is formed within the internal wall 40A. The external wall 40B is a cylindrical member that is provided outside the diameter of the internal wall 40A and surrounds the internal wall 40A along the entire periphery. The external wall 40B has substantially the same height as the tape width of the print medium. A first tape (the heat-sensitive paper tape 55 in the first embodiment) is wound on the outer periphery of the external wall 40B.

[0081] Connecting members 40C are provided radially from the center of the internal wall 40A and the external walls 40B in a plan view between the internal wall 40A and the external wall 40B. The connecting members 40C are plate-shaped members that are longer in the vertical direction. The first tape spool 40 is formed to have a double-cylinder configuration in which the internal wall 40A and the external wall 40B are coaxially connected by the connecting members 40C. The first tape spool 40 is supported by the cylindrical wall portion 85 inserted in the shaft hole 40D to be rotatable about its axis inside the cassette case 31. In the first tape spool 40, the opening width of the shaft hole 65C is substantially equal to or slightly larger than the diameter of the auxiliary shaft 110 in order to reduce looseness in the circumferential direction which may exist relative to the auxiliary shaft 110 inserted in the shaft hole 65C.

[0082] As shown in FIG. 11, the ribbon take-up spool 44 is rotatably supported by the take-up spool support hole 67 that extends through the cassette case 31 in the vertical direction. More specifically, the take-up spool support hole 67 includes an opening 67A and an opening 67B that are through-holes formed at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. The ribbon take-up spool 44 is formed in a cylindrical shape that has substantially the same height as the width (that is, the length in the vertical direction) of the cassette case 31. Flange-shaped support portions 44E that project outwardly along the entire periphery are provided at the upper edge and the lower edge of the ribbon take-up spool 44, respectively.

[0083] Inside the cassette case 31, an upper end 44A of the ribbon take-up spool 44 is fitted in the opening 67A of the top wall 35, and a lower end 44B of the ribbon take-up spool 44 is fitted in the opening 67B of the bottom wall 36. The support portion 44E provided at the upper edge

of the ribbon take-up spool 44 contacts with the top case 31A from below to regulate the movement of the ribbon take-up spool 44 in the upward direction. The support portion 44E provided at the lower edge of the ribbon take-up spool 44 contacts with the bottom case 31B from above to regulate the movement of the ribbon take-up spool 44 in the downward direction. Thus, the ribbon take-up spool 44 is supported at both ends 44A and 44B to be rotatable about its axis inside the cassette case 31.

[0084] A shaft hole 44C that extends in the vertical direction through the ribbon take-up spool 44 is formed inside the ribbon take-up spool 44. A plurality of latching ribs 44D are provided slightly below the center position in the vertical direction on the inner peripheral surface of the ribbon take-up spool 44 (that is, on the internal wall forming the shaft hole 44C). When the tape cassette 30 is installed in the cassette housing portion 8, the ribbon take-up shaft 95 described above is inserted in the shaft hole 44C via the opening 67B. Then, the latching ribs 44D provided in the ribbon take-up spool 44 are meshed with cam members 95A (refer to FIG. 14) formed around the ribbon take-up shaft 95. Thus, the rotation of the ribbon take-up shaft 95 is transmitted to the ribbon take-up spool 44 (that is, the ribbon take-up spool 44 rotates in concert with the rotation of the ribbon take-up shaft 95). The opening width of the shaft hole 44C is larger than the diameter of the ribbon take-up shaft 95 such that looseness may be allowed in the circumferential direction with respect to the ribbon take-up shaft 95 when the ribbon take-up shaft 95 is inserted in the ribbon take-up spool 44.

[0085] As shown in FIG. 12, the tape feed roller 46 is rotatably supported by the roller support hole 64 that extends through the cassette case 31 in the vertical direction. More specifically, the roller support hole 64 includes an opening 64A and an opening 64B both of which are through-holes formed at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. The regulating members 63 projecting toward each other are formed along the front edge of the cassette case 31 at each position near the openings 64A and 64B. The guide wall 38 is standing upward adjacent to and at the rear of the regulating members 63. The guide wall 38 extends between the top case 31A and the bottom case 31B. An interval between base ends of the regulating members 63 is set to be the same as the tape width of the print medium.

[0086] The tape feed roller 46 is formed in a cylindrical shape that has substantially the same height as the width (that is, the length in the vertical direction) of the cassette case 31. A main body 46E of the tape feed roller 46 has a larger diameter than the openings 64A and 64B and has a roller surface 46C. The roller surface 46C is an outer peripheral surface of the main body 46E that contacts the print medium. The length of the roller surface 46C in the vertical direction (that is, a tape feed width of the tape feed roller 46) is set to be the same as the tape width of the print medium. An upper end 46A and a lower

end 46B respectively project in the upward and downward directions from the main body 46E of the tape feed roller 46. The upper end 46A and the lower end 46B have a slightly smaller diameter than the openings 64A and 64B. The shaft hole 46D that extends through the main body 46E in the vertical direction connects both ends 46A and 46B inside the tape feed roller 46.

[0087] Inside the cassette case 31, the upper end 46A is fitted in the opening 64A of the top wall 35, and the lower end 46B is fitted in the opening 64B of the bottom wall 36. The main body 46E contacts with the top case 31A from below to regulate the movement of the tape feed roller 46 in the upward direction, and contacts with the bottom case 31B from above to regulate the movement of the tape feed roller 46 in the downward direction. Thus, the tape feed roller 46 is supported at both ends 46A and 46B to be rotatable about its axis inside the cassette case 31.

[0088] As shown in FIG. 17, a plurality of latching ribs 46F are provided at the lower end of the tape feed roller 46 on the inner periphery surface of the tape feed roller 46 (that is, on the internal wall forming the shaft hole 46D). When the tape cassette 30 is installed in the cassette housing portion 8, the tape drive shaft 100 described above is inserted in the shaft hole 46D via the opening 64B. Then, the latching ribs 46F provided in the tape feed roller 46 are meshed with the cam members 100A formed around the tape drive shaft 100. Thus, the rotation of the tape drive shaft 100 is transmitted to the tape feed roller 46 (that is, the tape feed roller 46 rotates in concert with the rotation of the tape drive shaft 100). The opening width of the shaft hole 46D is slightly larger than the diameter of the tape drive shaft 100 such that looseness may be slightly allowed in the circumferential direction with respect to the tape drive shaft 100 when the tape drive shaft 100 is inserted in the tape feed roller 46.

[0089] As shown in FIG. 13, the guide hole 47 that extends through the cassette case 31 in the vertical direction is formed at the rear right side of the cassette case 31. More specifically, the guide hole 47 includes an opening 47A and an opening 47B, and a shaft hole 47C which connects the openings 47A and 47B. The openings 47A and 47B are provided at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. Since the guide hole 47 is formed in the common portion 32 which is positioned at the rear right side of the cassette case 31 in a plan view, the opening 47B is formed in the lower surface of the common portion 32. A cylindrical wall portion 89 having a cylindrical shape extends between the top wall 35 and the bottom wall 36 (the lower surface of the common portion 32) inside the cassette case 31. The cylindrical wall portion 89 forms the shaft hole 47C connecting the openings 47A and 47B.

[0090] As shown in FIGS. 8 and 9, the second tape support hole 66 also includes a pair of openings 66A and 66B that are formed at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. A

pair of short cylindrical wall portions extends from the openings 66A and 66B toward each other inside the cassette case 31. The second tape spool (not shown in the figures) is a cylindrical member having substantially the same height as the tape width of the print medium and is wound with a second tape on its outer periphery surface. When the second tape is mounted in the cassette case 31, the short cylindrical wall portions extend from the openings 66A and 66B are respectively inserted in openings at both ends of the shaft hole which extends through the second tape spool in the vertical direction. Thus, the second tape spool is supported in the second tape support hole 66 to be rotatable about its axis inside the cassette case 31. The tape cassette 30 according to the first embodiment does not include the second tape spool inside the cassette case 31.

[0091] Similarly, the ribbon support hole 68 also includes a pair of openings 68A and 68B that are formed at positions opposing each other in the top wall 35 and the bottom wall 36, respectively. A pair of short cylindrical wall portions extends from the opening 68A and 68B toward each other inside the cassette case 31. The ribbon spool (not shown in the figures) is a cylindrical member having substantially the same height as the ribbon width of the ink ribbon, and is wound with an ink ribbon on its outer periphery surface. When the ink ribbon is mounted in the cassette case 31, the pair of short cylindrical wall portions extending from the openings 68A and 68B are respectively inserted in openings at both ends of the shaft hole which extends through the ribbon spool in the vertical direction. Thus, the ribbon spool is supported in the ribbon support hole 68 to be rotatable about the axial line inside the cassette case 31. The tape cassette 30 according to the first embodiment does not include the ribbon spool inside the cassette case 31.

[0092] The positional relationships among the respective portions provided in the tape cassette 30 according to the first embodiment will be explained with reference to FIGS. 3, 8 and 9. The two-dot chain line in FIGS. 8 and 9 indicates a division line K described later. The roller support hole 64, the guide hole 47, the first tape support hole 65, the take-up spool support hole 67, the pin hole 53 and the head insertion portion 39, which are described above, are formed at positions that oppose the tape drive shaft 100, the guide shaft 120, the auxiliary shaft 110, the ribbon take-up shaft 95, the positioning pin 102 and the head holder 74 in the cassette housing portion 8 when the tape cassette 30 is installed in the cassette housing portion 8, respectively.

[0093] The roller support hole 64 is formed in a first hole forming area 30A including a corner portion positioned at the front left portion of the tape cassette 30. More specifically, nine areas can be formed if the tape cassette 30, which is substantially rectangular in a plan view, is divided into three parts in its front-rear direction and left-right direction, respectively. The first hole forming area 30A is an area at the foremost and leftmost position among the nine areas. The first hole forming area 30A

is adjacent to the left side of the head insertion portion 39 provided at the center of the front portion of the tape cassette 30. In other words, the first hole forming area 30A is positioned on the downstream side of the head insertion portion 39 in the tape feed direction. Thus, when the tape cassette 30 is installed at a proper position in the cassette housing portion 8, the corner portion included in the first hole forming area 30A opposes the first shaft installation area 8C described above.

[0094] The guide hole 47 is formed in a second hole forming area 30B including a corner portion positioned at the rear right portion of the tape cassette 30. More specifically, the second hole forming area 30B is an area at the rearmost and rightmost position among the nine areas described above. In other words, when the tape cassette 30 is seen in a plan view, the corner portion included in the second hole forming area 30B is at a diagonal position with respect to the corner portion included in the first hole forming area 30A. Thus, when the tape cassette 30 is installed at a proper position in the cassette housing portion 8, the corner portion included in the second hole forming area 30B opposes the second shaft installation area 8D.

[0095] When the tape cassette 30 is divided in a plan view with reference to the division line K connecting the roller support hole 64 and the guide hole 47, two areas are formed. An area that occupies the part at the rear side of the division line K is a first housing area 30C. The other area that occupies the part at the front side of the division line K is a second housing area 30D. The first tape support hole 65 is formed at or in the vicinity of the center of gravity of the first housing area 30C forming a triangle shape in a plan view. The center of gravity of the first housing area 30C is the intersecting point of the three median lines of the triangular first housing area 30C. The take-up spool support hole 67 is formed at or in the vicinity of the center of gravity of the second housing area 30D forming a triangle shape in a plan view. The center of gravity of the second housing area 30D is the intersecting point of the three median lines of the triangular second housing area 30D. The first tape support hole 65 and the take-up spool support hole 67 are positioned substantially symmetrically across the division line K in a plan view.

[0096] The pin hole 53 that is indented upward at substantially the same depth as the height of the positioning pin 102 is formed adjacent to and at the rear side of the roller support hole 64 in the bottom case 31B. The tape cassette 30 installed in the cassette housing portion 8 is supported in the vicinity of the roller support hole 64 by the positioning pin 102 inserted in the pin hole 53, and is supported in the vicinity of the guide hole 47 by the positioning pin 103 contacting with the common portion 32.

[0097] The second tape support hole 66 is formed on the division line K in a plan view. More specifically, the second tape support hole 66 is positioned substantially at the middle between the center of the tape cassette 30

in a plan view and the guide hole 47. The ribbon support hole 68 is formed in the second housing area 30D. More specifically, the ribbon support hole 68 is positioned nearer to the front right side corner of the tape cassette 30 than the take-up spool support hole 67.

[0098] With the above positional relationships, the weight distribution of the tape cassette 30 according to the first embodiment can be explained as follows. The first tape spool 40 is rotatably supported around the first tape support hole 65 inside the tape cassette 30, as described above. This means that at least the center of rotation of the first tape spool 40 (that is, the shaft hole 40D) exists within the first housing area 30C in a plan view. In other words, this means that the center of gravity of the first tape (the heat-sensitive paper tape 55) wound on the first tape spool 40 is positioned within the first housing area 30C in a plan view.

[0099] On the other hand, the tape cassette 30 according to the first embodiment does not include another print medium (second tape) or an ink ribbon. In other words, in the tape cassette 30, the first housing area 30C in which the center of gravity of the heat-sensitive paper tape 55 is positioned is heavier than the second housing area 30D. A user may vertically insert the tape cassette 30 having such a weight distribution in the cassette housing portion 8 while maintaining the top wall 35 and the bottom wall 36 substantially horizontal with the fingers sandwiching the side wall 37 at the right and left sides, for example. At this time, due to a weight imbalance of the tape cassette 30, the first housing area 30C may be inclined downward with the division line K as the center of rotation.

[0100] With the tape printer 1 and the tape cassette 30 described above, when the tape cassette 30 is installed in the cassette housing portion 8, the three guide shafts (the tape drive shaft 100, the guide shaft 120 and the auxiliary shaft 110) standing upward in the cassette housing portion 8 can be inserted in the three guide holes (the roller support hole 64, the guide hole 47 and the first support hole 65) provided in the tape cassette 30, respectively. Thus, the tape cassette 30 can be guided to a proper position in the cassette housing portion 8. The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 will be described below in detail.

[0101] When the tape cassette 30 is installed at a proper position in the cassette housing portion 8, the tape drive shaft 100 is fitted in the tape feed roller 46 by insertion, and the ribbon take-up shaft 95 is fitted in the ribbon take-up spool 44 by insertion. Then, when the cassette cover 6 is closed, the platen holder 12 moves toward the print position, so that the platen roller 15 opposes the thermal head 10, and the movable feed roller 14 presses the tape feed roller 46. Thus, the tape printer 1 is in a state in which printing can be performed on the print medium.

[0102] When the platen holder 12 moves from the standby position toward the print position, the switch por-

tion 20 provided in the platen holder 12 opposes the arm indicator portion 80 provided in the tape cassette 30. At this time, if the tape cassette 30 is installed at the proper position of the cassette housing portion 8, each of the detecting switches 21 enters an ON state or an OFF state, depending on a pattern of the indicators (the non-pressing portion 81 and the pressing portion 82) included in the arm indicator portion 80. More specifically, the detecting switch 21 that opposes the non-pressing portion 81 is inserted in the non-pressing portion 81 to enter the OFF state. The detecting switch 21 that opposes the pressing portion 82 is pressed by the pressing portion 82 to enter the ON state.

[0103] In the tape printer 1, the information on the tape cassette 30 is obtained based on a combination of the ON and OFF states of the detecting switches 21. The tape cassette 30 according to the first embodiment is a general purpose cassette that can be assembled as various types, but is actually assembled as a thermal type tape cassette that houses only the heat-sensitive paper tape 55 as the print medium. Thus, in the tape printer 1, "thermal type with tape width of 36 mm" is detected as a type of the tape cassette 30, for example, based on the detection result in the switch portion 20.

[0104] In the first embodiment, while printing is being performed in the tape printer 1, the tape feed roller 46 that is driven to rotate via the tape drive shaft 100 pulls out the heat-sensitive paper tape 55 from the first tape spool 40 in concert with the movable feed roller 14. The heat-sensitive paper tape 55 that has been pulled out from the first tape spool 40 passes the right side of the ribbon support hole 68 to be fed along the feed path within the arm portion 34. Further, the heat-sensitive paper tape 55 is supplied from the exit 34A of the arm portion 34 to the head insertion portion 39 to be fed between the thermal head 10 and the platen roller 15. Then, characters are printed onto the print surface of the heat-sensitive paper tape 55 by the thermal head 10. Following that, the printed heat-sensitive paper tape 55 is further fed toward the tape discharge aperture 49 by the tape feed roller 46 in concert with the movable feed roller 14, and is cut by the cutting mechanism 17.

[0105] While the printing is being performed, the ribbon take-up spool 44 is also driven to rotate via the ribbon take-up shaft 95. However, the tape cassette 30 according to the first embodiment does not include a ribbon spool in the cassette case 31. For that reason, the ribbon take-up spool 44 does not pull out the unused ink ribbon, nor does it take up the used ink ribbon. In other words, even when the thermal type tape cassette 30 is used in the tape printer 1 that is equipped with the ribbon take-up shaft 95, the rotation drive of the ribbon take-up shaft 95 does not have an influence on the printing operation onto the heat-sensitive paper tape 55 and printing can be correctly performed. In the above tape cassette 30, the ribbon take-up spool 44 may not be provided and the ribbon take-up shaft 95 may perform idle running inside the take-up spool support hole 67 in a similar manner.

[0106] The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 according to the first embodiment will be described with reference to FIGS. 14 to 18. In FIGS. 14 to 16 that show the right side surface of the tape cassette 30, only the holes associated with the installation and removal of the tape cassette 30 are illustrated in a two-dot chain line for ease of understanding. In addition, in FIGS. 14 to 16 that also show the schematic section views of the cassette housing portion 8 as seen from the right side thereof, only the shafts associated with the installation and removal of the tape cassette 30 are illustrated for ease of understanding. In FIG. 16, only the guide hole 47 and its vicinity are shown in a section as seen from the right side of the tape cassette 30.

[0107] The relationships in the vertical direction among the respective members standing upward in the cassette housing portion 8 will be explained. In the first embodiment, the head holder 74, the tape drive shaft 100, the ribbon take-up shaft 95, the auxiliary shaft 110 and the guide shaft 120 each have a height (lengths in the vertical direction) at least larger than the height T of the common portion 32. Three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120) among the shafts have a substantially same height. In addition, the height of each of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 is longer than the height of the ribbon take-up shaft 95 and the height of the head holder 74.

[0108] For that reason, in a state in which the head holder 74, the tape drive shaft 100, the ribbon take-up shaft 95 and the auxiliary shaft 110 are standing upward, with reference to the height position on the planar portion of the cavity 8A, the height positions of the upper ends of the tape drive shaft 100 and the auxiliary shaft 110 are the highest. The height position of the upper end of the head holder 74 is the second highest. The height position of the upper end of the ribbon take-up shaft 95 is the lowest. The height position of the upper end of the ribbon take-up shaft 95 is substantially the same as the height position of the upper end of the thermal head 10 fixed to the head holder 74.

[0109] The guide shaft 120 is standing upward on the cassette support portion 8B positioned above the cavity 8A, as described above. The upper end of the guide shaft 120 is at a height position higher than the upper end of any of the head holder 74, the tape drive shaft 100, the ribbon take-up shaft 95 and the auxiliary shaft 110. The height (the length in the vertical direction) from each upper end of the tape drive shaft 100 and the auxiliary shaft 110 to the upper end of the guide shaft 120 is substantially equal to the height (the length in the vertical direction) from the lower surface of the bottom wall 36 of the tape cassette 30 to the lower surface of the common portion 32. In other words, the thickness of the tape cassette 30 is made smaller due to the common portion 32 formed like steps, and thus the guide shaft 120 correspondingly extends above the height positions of the tape drive shaft

100 and the auxiliary shaft 110.

[0110] As shown in FIG. 14, when the user installs the tape cassette 30 in the cassette housing portion 8, the user positions the tape cassette 30 such that the relative positions in a plan view of the roller support hole 64, the first tape support hole 65 and the guide hole 47 substantially match those of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120, respectively. Then, the user vertically inserts the tape cassette 30 in the cassette housing portion 8, while maintaining the top wall 35 and the bottom wall 36 substantially horizontal, as described above. As the tape cassette 30 is moved down toward the cassette housing portion 8, as shown in FIG. 15, the respective upper ends of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 enter the openings 64B, 65B and 47B provided at the bottom wall 36 of the tape cassette 30, respectively. On the other hand, since the respective upper ends of the head holder 74 and the ribbon take-up shaft 95 are positioned below the bottom wall 36, the head holder 74 and the ribbon take-up shaft 95 do not enter the interior of the tape cassette 30.

[0111] When the tape cassette 30 is moved further down from the state shown in FIG. 15, the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are inserted in the shaft holes 46D, 65C and 47C via the openings 64B, 65B and 47B from below, respectively. The tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 respectively inserted in the shaft holes 46D, 65C and 47C are regulated in their movement in the circumferential direction by the internal walls of the respective shaft holes 46D, 65C and 47C to enter a slidable state along the standing direction (that is, in the vertical direction). In other words, the tape cassette 30 is guided along the standing direction of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 inserted in the shaft holes 46D, 65C and 47C, respectively, and moves down due to its own weight.

[0112] The upper edges of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are tapered such that the diameters become smaller toward the upper ends. For that reason, even when the roller support hole 64, the first tape support hole 65 and the guide hole 47 are slightly offset in the relative positions in a plan view, the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 can be inserted in the respective holes correctly and smoothly. In addition, the diameter of the tape drive shaft 100 is slightly smaller than the opening width of the tape feed roller 46 (the shaft hole 46D). Therefore, even if the horizontal position of the tape feed roller 46 is slightly changed within the roller support hole 64 due to vibration, inclination or the like, the tape drive shaft 100 can be smoothly inserted therein.

[0113] Further, as described above, the opening width of the guide hole 47 is larger than the diameter of the leading end of the guide shaft 120 (the small-diameter shaft portion 120B described above) and particularly the opening width in the left-right direction thereof is larger

than the opening width in the front-rear direction. Thus, when the tape cassette 30 is installed, the guide shaft 120 can be inserted in the guide hole 47 even if the relative position of the guide hole 47 with respect to the guide shaft 120 is slightly offset in the left-right direction in a plan view.

[0114] With above-described configuration, the holes (the roller support hole 64, the first tape support hole 65, and the guide hole 47) of the tape cassette 30 do not need to be accurately positioned corresponding to the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110, and the guide shaft 120) provided in the cassette housing portion 8. Therefore, the user's load can be reduced at the installation of the tape cassette 30. A high-level dimensional accuracy may be required for a worker in order to completely match the dimensional widths of the roller support hole 64 and the guide hole 47 with the dimensional widths of the tape drive shaft 100 and the guide shaft 120 when the tape cassette 30 is manufactured. In that respect, by giving looseness in the left-right direction in the guide hole 47, a slight error of the dimensional accuracy in forming the guide hole 47 may be acceptable. Therefore, the worker's load at the time of manufacturing the tape cassette 30 can be also reduced.

[0115] As the tape cassette 30 is guided downward, the head holder 74 having the thermal head 10 is inserted in the head insertion portion 39 from below, and the ribbon take-up shaft 95 is inserted in the shaft hole 44C via the opening 67B from below. As described above, since looseness is given in the head insertion portion 39 even if the head holder 74 is installed therein, the head holder 74 enters the loosely inserted state in which the head holder 74 can be displaced within the head insertion portion 39 in the front-rear direction and the left-right direction. In addition, since the opening width of the ribbon take-up spool 44 (the shaft hole 44C) is larger than the diameter of the ribbon take-up shaft 95, the ribbon take-up shaft 95 enters the loosely inserted state in which the ribbon take-up shaft 95 can displace within the ribbon take-up spool 44 in the circumferential direction.

[0116] As shown in FIG. 16, as the tape cassette 30 is moved further down along the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120, the positioning pin 103 standing upward on the cassette support portion 8B contacts the lower surface of the common portion 32 provided at the rear right portion of the tape cassette 30. At the same time, although not shown in FIG. 16, the positioning pin 102 standing upward on the cassette support portion 8B is inserted in the pin hole 53 and the upper end of the positioning pin 102 contacts the ceiling wall of the interior of the pin hole 53. In other words, the height position of the tape cassette 30 installed in the cassette housing portion 8 is defined at the height position at which the tape cassette 30 is supported by the positioning pins 102 and 103.

[0117] At the same time, the base end side (the large-diameter shaft portion 120A described above) of the

guide shaft 120 is fitted in the guide hole 47 (the shaft hole 47C) while being guided along the taper portion 120C. As described above, since the diameter of the large-diameter shaft portion 120A is substantially equal to the opening width of the guide hole 47, the large-diameter shaft portion 120A is tightly engaged with the guide hole 47 in the front-rear direction. Consequently, the guide shaft 120 is regulated in its displacement in the circumferential direction (particularly, in the front-rear direction) of the guide shaft 120. In addition, the positioning pin 102 is engaged within the pin hole 53 and is regulated in its displacement in the circumferential direction of the positioning pin 102. In other words, the horizontal position of the tape cassette 30 installed in the cassette housing portion 8 is defined at the horizontal position at which the tape cassette 30 is engaged by the guide shaft 120 and the positioning pin 102.

[0118] Printing by the thermal head 10 is performed in the direction perpendicular to the tape feed direction (i.e. the front-rear direction of the tape cassette 30). For that reason, it may be preferable that the installation position of the tape cassette 30 in the front-rear direction is accurately defined in order to prevent an offset of a printing position on the tape. On the other hand, even if the installation position of the tape cassette 30 is slightly offset along the tape feed direction (the left-right direction of the tape cassette 30), the offset may not have a large influence on the print quality. Since slight looseness is given around the large-diameter shaft portion 120A in the left-right direction when the guide shaft 120 is inserted in the guide hole 47 according to the first embodiment, the tape cassette 30 may be smoothly installed and removed while maintaining the print quality.

[0119] In this way, in the first embodiment, the tape cassette 30 is guided downward to a proper position in the cassette housing portion 8 by the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120). Then, the tape cassette 30 is positioned at a proper horizontal position by the guide shaft 120 and the positioning pin 102, and is positioned at a proper height position by the positioning pins 102 and 103. As shown in FIG. 17, in the state in which the tape cassette 30 is positioned at the proper position, the cam members 100A provided at the base end side of the tape drive shaft 100 are properly meshed with the latching ribs 46F of the tape feed roller 46. In addition, as shown in FIG. 18, the cam members 95A provided in the ribbon take-up shaft 95 are properly meshed with the latching ribs 44D of the ribbon take-up spool 44. Furthermore, the thermal head 10 provided on the head holder 74 is arranged at a proper print position in the head insertion portion 39. In this state, as described above, the tape printer 1 can appropriately perform printing on the print medium.

[0120] When the tape cassette 30 is removed from the cassette housing portion 8, the user may pull out the tape cassette 30 upward from the cassette housing portion 8 with the fingers sandwiching the side wall 37 at both the right and left sides. Also at this time, the tape cassette

30 is guided in the upward direction by the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120). Thus, the tape cassette 30 may be less likely to be inclined and caught at an internal wall and the like of the cassette housing portion 8 while the tape cassette 30 is removed from the cassette housing portion 8.

[0121] The tape cassette 30 according to the first embodiment has a weight distribution such that the first housing area 30C may be inclined downward. Therefore, the first housing area 30C is provided with the first tape support hole 65 that passes through the center of gravity of the first tape (the heat-sensitive paper tape 55), and the tape printer 1 is provided with the auxiliary shaft 110 to be inserted in the first tape support hole 65. When the tape cassette 30 is installed or removed, the first housing area 30C, which may cause a raised or inclined state of the tape cassette 30 inside the cassette housing portion 8, is guided in the vertical direction by the auxiliary shaft 110 inserted in the first tape support hole 65. For that reason, the raised or inclined state of the tape cassette 30 due to a downward inclination of the first housing area 30C may be restricted when the tape cassette 30 is installed.

[0122] In the first embodiment, the tape cassette 30 is guided in the vertical direction at the three points, that is, a pair of corner portions on a diagonal of the tape cassette 30 (specifically, the roller support hole 64 and the guide hole 47) and the center of gravity of the first tape (specifically, the first tape support hole 65) in a plan view. For that reason, a positional displacement or an inclination may be appropriately prevented when the tape cassette 30 is installed in the cassette housing portion 8. It may be preferable that the center of gravity of the entire tape cassette 30 is positioned within an area defined by connecting the roller support hole 64, the first tape support hole 65 and the guide hole 47 in a plan view. In such a case, the own weight of the tape cassette 30 is uniformly distributed to and acts on the three points, that is, the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120, by which the tape cassette 30 is guided. Then, the tape cassette 30 can smoothly move in the installation/ removal direction and the positional displacement or the inclination may be more reliably prevented in the process of the installation of the tape cassette 30.

[0123] The tape cassette 30 has four corner portions in a plan view. While the tape cassette 30 is installed or removed, the tape cassette 30 is guided at least at two points, that is, the front left corner portion at which the roller support hole 64 is provided and the rear right corner portion which is diagonal to the front left corner portion and at which the guide hole 47 is provided. At and in the vicinity of the front left corner portion of the tape cassette 30, tape feeding is performed by the tape feed roller 46 and printing is performed by the thermal head 10. In addition, the tape is exposed to the outside from the cassette case 31 for tape feeding and printing. For that reason, the positioning of the tape cassette 30 at the front

left corner portion may have a large influence on the print quality or tape feeding. In order to perform tape feeding by the tape feed roller 46, the tape drive shaft 100 that rotates the tape feed roller 46 is used.

[0124] Considering the above-described conditions, with the configuration in which the tape cassette 30 is guided in the installation/removal direction at the front left corner portion, the tape cassette 30 may be accurately positioned in the vicinity of the position at which the tape feeding and printing is performed. This configuration may also prevent a failure (that is, a so-called jam) in which the tape exposed to the outside tangles with other members in the installation process of the tape cassette 30. If the tape drive shaft 100 is utilized as one of guide shafts, as in the first embodiment, an additional shaft that guides the front left corner portion of the tape cassette 30 does not need to be separately provided. Therefore, the configuration of the tape printer 1 may be simplified. Further, with the configuration in which the tape cassette 30 is additionally guided at the rear right corner portion in the installation/removal direction, the tape cassette 30 may be stably guided in the installation/removal direction at the diagonal corner portions, which make the largest distance between two points in the tape cassette 30 in a plan view.

[0125] When the tape cassette 30 is installed at the proper position, the division line J and the division line K substantially match with each other in a plan view (refer to FIGS. 5 and 6). Then, the tape cassette 30 is fitted in the cavity 8A and the common portion 32 is supported above the cassette support portion 8B without an inclination or a positional displacement in the cassette housing portion 8. The thermal head 10 fixed on the head holder 74 is arranged at a correct print position within the head insertion portion 39. The tape drive shaft 100 and the ribbon take-up shaft 95 are appropriately inserted and fitted in the tape feed roller 46 and the ribbon take-up spool 44, respectively, without a shaft offset. The switch portion 20 (a plurality of detecting switches 21) provided in the platen holder 12 opposes the arm indicator portion 80 (the non-pressing portion 81 and the pressing portion 82) provided in the arm side wall 33 without a positional displacement, and a type of the tape cassette 30 is accurately detected. For that reason, in the tape printer 1, a possibility of a feeding failure of a tape or an ink ribbon, or a printing failure of the thermal head 10 may be remarkably reduced, and thus, correct printing may be performed.

[0126] In the first embodiment, the general purpose cassette assembled as the thermal type tape cassette 30 is used in the general purpose tape printer 1. Thus, a single tape printer 1 can be used with various types of the tape cassette 30 such as the thermal type, the receptor type and the laminated type. In other words, it may not be necessary to use the different tape printer for each type. Furthermore, when the tape cassette is manufactured, the cassette case is normally formed by injecting plastic into a plurality of combined dies. In the case of

the tape cassettes that correspond to the same tape width, common dies can be used except for the die including the portion that forms the arm indicator portion 80. Thus, costs may be significantly reduced. When a thermal type tape cassette is assembled considering the above advantages, it may be effective that the long heat-sensitive paper tape 55 is wound on the first tape spool 40 and housed in the general purpose cassette case, as in the first embodiment.

[0127] In the first embodiment, the thermal type tape cassette 30 formed from a general purpose cassette is used in the general purpose tape printer 1. However, a dedicated tape cassette for the thermal type may be configured, or the tape cassette 30 of the first embodiment may be used in a dedicated tape printer for the thermal type.

[0128] For example, as shown in FIGS. 19 and 21, a tape printer 1 dedicated for the thermal type may be configured. An ink ribbon is not used for printing on the print medium with the thermal type. Therefore, if the tape printer 1 is a dedicated device in which only the thermal type tape cassette 30 is used, the tape printer 1 may not include the ribbon take-up shaft 95 for rotating the ribbon take-up spool 44. For that reason, the ribbon take-up shaft 95 is not standing upward on the gear 94 (refer to FIG. 3).

[0129] As shown in FIGS. 20 and 21, a dedicated tape cassette 30 for the thermal type capable of housing only the heat-sensitive paper tape may be configured; this tape cassette 30 shown in Fig. 21, however is not covered by the claims. If the tape cassette 30 is dedicated for the thermal type, the tape cassette 30 may not be configured to house other print medium or an ink ribbon. For that reason, the tape cassette 30 shown in FIGS. 20 and 21 has none of the second tape spool and the second tape support hole 66 for supporting the second tape spool, the ribbon take-up spool 44 and the take-up spool support hole 67 for supporting the ribbon take-up spool 44, and the ribbon spool and the ribbon support hole 68 for supporting the ribbon spool.

[0130] Even when such a configuration is employed, the tape cassette 30 may be installed in and removed from the tape printer 1 in a similar manner as described above. Specifically, the three guide shafts (the tape drive shaft 100, the guide shaft 120 and the auxiliary shaft 110) are inserted in the three corresponding guide holes (the roller support hole 64, the guide hole 47 and the first tape support hole 65), respectively, so that the tape cassette 30 is guided to a proper position of the cassette housing portion 8 (refer to FIG. 22).

[0131] In the dedicated tape cassette 30 for the thermal type shown in FIGS. 20 and 21, the weight of the first housing area 30C is further heavier relative to the second housing area 30D, due to an absence of the ribbon take-up spool 44 and the like in the second housing area 30D, as compared to the general purpose tape cassette 30 shown in FIGS. 8 and 9. Therefore, the first housing area 30C may be inclined downward more easily when the

tape cassette 30 is installed, and thus the tape cassette 30 may be inclined or raised in the cassette housing portion 8 more easily. According to the first embodiment, the auxiliary shaft 110 is inserted in the guide hole 47 that passes through the first housing area 30C as described above so that the tape cassette 30 is guided while being installed or removed. For that reason, even if the weight of the first housing area 30C is heavier in the tape cassette 30, the tape cassette 30 may be prevented from being inclined or raised.

[0132] In the first embodiment, the auxiliary shaft 110 that has a slightly smaller diameter than the opening width of the shaft hole 65C is inserted or removed at the center of the opening of the shaft hole 65C of the first tape support hole 65 in a plan view (refer to FIGS. 5, 6 and the like). However, the auxiliary shaft 110 may be positioned in a direction in which the tape cassette 30 to be installed in or removed from the cassette housing portion 8 is likely to incline and contact the internal peripheral surface of the shaft hole 65C in a plan view.

[0133] For example, the auxiliary shaft 110 shown in FIG. 23 has a smaller diameter than the opening width of the shaft hole 65C (about half of the shaft hole 65C). Moreover, the auxiliary shaft 110 shown in FIG. 23 is positioned at the upper left side of the center of the opening of the shaft hole 65C in a plan view when the tape cassette 30 is installed in the cassette housing portion 8. The auxiliary shaft 110 has a smaller diameter than the opening width of the shaft hole 65C, and contacts the rear left portion in a plan view of the internal peripheral surface of the shaft hole 65C (hereinafter referred to as the rear left side surface). For that reason, when the tape cassette 30 is installed or removed, in a similar manner as the first embodiment, the auxiliary shaft 110 contacts the internal peripheral surface of the shaft hole 65C so that the tape cassette 30 is guided along the auxiliary shaft 110 while being installed or removed.

[0134] When the tape cassette 30 is guided along the two guide shafts (the tape drive shaft 100 and the guide shaft 120), a direction in which the tape cassette 30 is likely to incline during the installation/removal is a direction F (one-dot chain line in FIG. 23), which is perpendicular to the division line K. The rear left side surface of the shaft hole 65C which the auxiliary shaft 110 shown in FIG. 23 contacts is at the furthest position from the center of rotation (the division line K) in the direction F in a plan view.

[0135] In other words, the auxiliary shaft 110 shown in FIG. 23 defines a proper horizontal position of the first tape support hole 65 by the distance from the division line K in a plan view. The auxiliary shaft 110 contacts the rear left side surface of the shaft hole 65C so that the tape cassette 30 is prevented from inclining in the direction F with the division line K as the center of rotation in a plan view. In FIG. 23, the auxiliary shaft 110 is positioned at the rear left side of the center of the opening of the shaft hole 65C, but even if the auxiliary shaft 110 is positioned in other direction (for example, at the left side

or rear side of the center of the opening of the shaft hole 65C) in which the tape cassette 30 is likely to incline, similar effects as described above may be obtained.

5 < Second embodiment; the tape cassette according to Fig. 26, 30, 31 is not covered by the claims >

[0136] The tape printer 1 and the tape cassette 30 according to a second embodiment will be explained with reference to FIGS. 24 to 31. The second embodiment describes an example in which the tape cassette 30 houses one tape (specifically, a non-heat-sensitive print tape as a print medium) and an ink ribbon, and has two guide holes for guiding the tape cassette 30 when the tape cassette 30 is installed in or removed from the tape printer 1. The second embodiment also describes an example in which the tape printer 1 has two guide shafts for guiding the tape cassette 30 to a proper position corresponding to the two guide holes described above.

[0137] As shown in FIGS. 24 to 26, the tape printer 1 according to the second embodiment is a general purpose device that can commonly use a plurality of types of tape cassettes 30 with various tape types, similar to the tape printer 1 according to the first embodiment (refer to FIGS. 1 to 7). However, the tape printer 1 according to the second embodiment is different from the tape printer 1 according to the first embodiment in that the auxiliary shaft 110 is not provided.

[0138] As shown in FIG. 24, the tape cassette 30 according to the second embodiment is a general purpose cassette that may be assembled as various types, similar to the tape cassette 30 according to the first embodiment (refer to FIGS. 3 and 7 to 13). As shown in FIG. 26, in the tape cassette 30 according to the second embodiment, the first tape spool 40 is rotatably supported by the first tape support hole 65. A non-heat-sensitive print tape 57 as the first tape is wound on the first tape spool 40. In addition, a ribbon spool 42 is rotatably supported by the ribbon support hole 68 and an ink ribbon 60 to be used for printing on the print tape 57 is wound on the ribbon spool 42. In other words, the tape cassette 30 according to the second embodiment is assembled as a so-called receptor type tape cassette. The receptor type tape cassette 30 does not need to house other print medium, and thus does not include the second tape spool on which the second tape is wound.

[0139] In the tape printer 1 and the tape cassette 30 described above, when printing is performed in the tape printer 1, the tape feed roller 46 that is driven to rotate via the tape drive shaft 100 pulls out the print tape 57 from the first tape spool 40 in concert with the movable feed roller 14. Further, the ribbon take-up spool 44, which is driven to rotate via the ribbon take-up shaft 95, pulls out an unused ink ribbon 60 from the ribbon spool 42 in synchronization with the print speed.

[0140] The print tape 57 that has been pulled out from the first tape spool 40 passes the right side of the ribbon support hole 68 i to be fed along the feed path within the

arm portion 34. The print tape 57 is supplied from the exit 34A to the head insertion portion 39 in a state in which the ink ribbon 60 is joined to the surface of the print tape 57. The print tape 57 is fed between the thermal head 10 and the platen roller 15 of the tape printer 1. Then, characters are printed on the print surface of the print tape 57 by the thermal head 10. Thereafter, the used ink ribbon 60 is peeled off from the printed print tape 57 at the guide wall 38 and is taken up on the ribbon take-up spool 44. On the other hand, the printed print tape 57 is further fed toward the tape discharge aperture 49, discharged from the discharge aperture 49, and cut by the cutting mechanism 17.

[0141] As shown in FIGS. 8, 9 and 26, the positional relationships among the respective portions provided in the tape cassette 30 according to the second embodiment are similar to the first embodiment but are different in the following points. Specifically, the first tape spool 40 on which the print tape 57 is wound is rotatably supported by the first tape support hole 65. For that reason, the center of gravity of the print tape 57 is positioned within the first housing area 30C in a plan view. On the other hand, the ribbon spool 42 on which the unused ink ribbon 60 is wound is rotatably supported by the ribbon support hole 68. The ribbon take-up spool 44 on which the used ink ribbon 60 is wound is rotatably supported by the take-up spool support hole 67. For that reason, the center of gravity of the ink ribbon 60 is positioned within the second housing area 30D in a plan view.

[0142] With the above positional relationships, in the tape cassette 30 according to the second embodiment, the weights of the first housing area 30C and the second housing area 30D defined by the division line K are close to each other. A user may vertically insert the tape cassette 30 having such a weight distribution in the cassette housing portion 8, while maintaining the top wall 35 and the bottom wall 36 substantially horizontal with the fingers sandwiching the side wall 37 at both the right and left sides. At this time, weight imbalance in the tape cassette 30 is little so that the tape cassette 30 may be prevented from inclining with the division line K as the center of rotation. Although the print tape 57 is generally heavier than the ink ribbon 60, the difference in weight between the first housing area 30C and the second housing area 30D becomes much smaller due to the weight of the ribbon take-up spool 44 housed in the second housing area 30D. In other words, the weight imbalance of the tape cassette 30 is reduced.

[0143] The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 according to the second embodiment will be explained with reference to FIGS. 27 and 28. The relationships in the vertical direction among the respective portions standing upward in the cassette housing portion 8 are similar to the first embodiment except for the absence of the auxiliary shaft 110.

[0144] When the user installs the tape cassette 30 in the cassette housing portion 8, the user positions the

tape cassette 30 such that the relative positions in a plan view of the roller support hole 64 and the guide hole 47 substantially match those of the tape drive shaft 100 and the guide shaft 120, respectively. Then, the user vertically inserts the tape cassette 30 in the cassette housing portion 8, while maintaining the top wall 35 and the bottom wall 36 substantially horizontal, as described above. When the tape cassette 30 is moved down toward the cassette housing portion 8, as shown in FIG. 27, the upper ends of the tape drive shaft 100 and the guide shaft 120 enter the openings 64B and 47B provided at the bottom wall 36 of the tape cassette 30 substantially at the same time, respectively.

[0145] When the tape cassette 30 is moved further down from the state shown in FIG. 27, the tape drive shaft 100 and the guide shaft 120 are inserted in the shaft holes 46D and 47C via the openings 64B and 47B from below, respectively. Then, the tape cassette 30 is guided along the standing direction (that is, the vertical direction) of the tape drive shaft 100 and the guide shaft 120 inserted in the shaft holes 46D and 47C, respectively, and moves down due to its own weight. Then, the head holder 74 having the thermal head 10 is inserted in the head insertion portion 39, and the ribbon take-up shaft 95 is inserted in the shaft hole 44C via the opening 67B from below.

[0146] As shown in FIG. 28, as the tape cassette 30 is moved down along the tape drive shaft 100 and the guide shaft 120, the positioning pin 103 standing upward on the cassette support portion 8B contacts the lower surface of the common portion 32 provided at the rear right portion of the tape cassette 30. At the same time, although not shown in FIG. 28, the positioning pin 102 standing upward on the cassette support portion 8B is inserted in the pin hole 53, and the upper end of the positioning pin 102 contacts the ceiling wall of the interior of the pin hole 53. In this manner, in the second embodiment, the tape cassette 30 is guided to a proper position of the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120). Then, the tape cassette 30 is positioned at a proper horizontal position by the guide shaft 120 and the positioning pin 102, and is positioned at a proper height position by the positioning pins 102 and 103. Also when the tape cassette 30 is removed from the cassette housing portion 8, the tape cassette 30 is guided upward along the two guide shafts.

[0147] The guide hole 47 according to the second embodiment has an ellipse-shaped opening having a long diameter (major axis) in the left-right direction and a short diameter (minor axis) in the front-rear direction in a plan view. The diameters (the major axis and the minor axis) of the guide hole 47 are both larger than the diameter of the small-diameter shaft portion 120B of the guide shaft 120. The opening width of the guide hole 47 in the left-right direction is larger than the opening width in the front-rear direction. Since a length of the minor axis of the guide hole 47 is substantially equal to the diameter of the

large-diameter shaft portion 120A of the guide shaft 120, the guide shaft 120 is inserted in the guide hole 47 to be tightly engaged with the large-diameter shaft portion 120A in the front-rear direction while looseness is allowed in the left-right direction of the large-diameter shaft portion 120A. Thus, similar to the first embodiment, the corresponding holes (the roller hole 64 and the guide hole 47) of the tape cassette 30 do not need to be accurately positioned with respect to all the two guide shafts (the tape drive shaft 100 and the guide shaft 120) provided in the cassette housing portion 8. Thus, the user's load may be reduced when the user installs the tape cassette 30. Further, the tape cassette 30 can be smoothly installed and removed while maintaining the print quality.

[0148] The tape cassette 30 according to the second embodiment has a weight distribution such that the weights of the first housing area 30C and the second housing area 30D are close to each other. For that reason, an inclination due to the own weight of the tape cassette 30 may be less likely to occur in the process of the installation of the tape cassette 30 in the cassette housing portion 8. Thus, even when the auxiliary shaft 110 is not provided, unlike the first embodiment, the tape cassette 30 may be guided to a proper position in the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120).

[0149] Furthermore, the tape cassette 30 is guided in the vertical direction at the two points, that is, a pair of corner portions on a diagonal of the tape cassette 30 (specifically, the roller support hole 64 and the guide hole 47) in a plan view. In other words, the tape cassette 30 is guided in the installation/removal direction about the division line K that passes between the center of gravity of the print tape 57 and the center of gravity of the ink ribbon 60. For that reason, a positional displacement or an inclination may be appropriately prevented when the tape cassette 30 is installed in the cassette housing portion 8.

[0150] In the second embodiment, the receptor type tape cassette 30 formed from a general purpose cassette is used in the general purpose tape printer 1. However, a dedicated tape cassette for the receptor type may be configured, or the tape cassette 30 of the second embodiment may be used in a dedicated tape printer for the receptor type.

[0151] For example, as shown in FIGS. 29 and 30, a dedicated tape cassette 30 for the receptor type capable of housing only a print tape 57 and an ink ribbon 60. This tape cassette 30 shown in Fig. 30 is not covered by the claims. If the tape cassette 30 is dedicated for the receptor type, the tape cassette 30 may not be configured to house other print medium. For that reason, the tape cassette 30 shown in FIGS. 29 and 30 has none of the second tape spool and the second tape support hole 66 for supporting the second tape spool.

[0152] Moreover, since the tape printer 1 according to the second embodiment does not include the auxiliary shaft 110, the first tape support hole 65 in which the aux-

iliary shaft 110 is to be inserted may not be provided in the tape cassette 30. For example, as shown in FIG. 29, a cylindrical wall portion 65D that rotatably supports the first tape spool 40 within the cassette case 31 may be provided between the top wall 35 and the bottom wall 36, instead of the first tape support hole 65.

[0153] Also with such a configuration, the tape cassette 30 can be installed in and removed from the tape printer 1 in a similar manner as in the second embodiment. Specifically, the two guide shafts (the tape drive shaft 100 and the guide shaft 120) are inserted in the two corresponding guide holes (the roller support hole 64 and the guide hole 47), respectively, so that the tape cassette 30 is guided to a proper position in the cassette housing portion 8 (refer to FIG. 28).

[0154] In the second embodiment, the weight distribution of the tape cassette 30 is adjusted with the configuration in which the center of gravity of the print tape 57 is positioned in the first housing area 30C and the center of gravity of the ink ribbon 60 is positioned in the second housing area 30D. However, the weight of the print tape 57 varies depending on a thickness of the tape or of a material of the tape. For example, when the print tape 57 that is heavy due to its material nature or the like is used, the center of gravity of the tape cassette 30 may not be positioned on the line connecting the two guide holes (the roller support hole 64 and the guide hole 47), and may shift toward the side of the first housing area 30C.

[0155] In this case, as shown in FIG. 31, the tape cassette 30 may be provided with the first tape support hole 65 (refer to FIG. 24) and the tape printer 1 may be provided with the auxiliary shaft 110 (refer to FIGS. 3, 4 and the like) as in the case of the first embodiment. With this configuration, the tape cassette 30 may be guided not only by the two guide shafts (the tape drive shaft 100 and the guide shaft 120) but also by the auxiliary shaft 110 when installed in and removed from the cassette housing portion 8, similar to the first embodiment (refer to FIGS. 14 to 16). In other words, even when the center of gravity of the entire tape cassette 30 is shifted toward the side of the first housing area 30C due to the heavy print tape 57, the tape cassette 30 may be smoothly installed in the cassette housing portion 8 similar to the first embodiment.

<Third embodiment>

[0156] The tape printer 1 and the tape cassette 30 according to a third embodiment will be explained with reference to FIGS. 32 to 35. The third embodiment describes an example in which the tape cassette 30 houses a tape (specifically, a heat-sensitive paper tape as a print medium) therein, and has two guide holes for guiding the tape cassette 30 when the tape cassette 30 is installed in or removed from the tape printer 1. The third embodiment also describes an example in which the tape printer 1 has two guide shafts for guiding the tape cassette 30 to a proper position corresponding to the two guide holes

described above.

[0157] As shown in FIG. 32, the tape printer 1 according to the third embodiment is a general purpose device that can commonly use a plurality of tape cassettes 30 with various tape types. Similar to the tape printer 1 according to the second embodiment (refer to FIGS. 24 to 26), the tape printer 1 according to the third embodiment is not provided with the auxiliary shaft 110 unlike the first embodiment.

[0158] The tape cassette 30 according to the third embodiment is a general purpose cassette that can be assembled as various types, similar to the tape cassette 30 according to the first embodiment (refer to FIGS. 3 and 7 to 13). As shown in FIG. 32, in the tape cassette 30 according to the third embodiment, the second tape spool 41 is rotatably supported by the second tape support hole 66, and the heat-sensitive paper tape 55 as the second tape is wound on the second tape spool 41. In other words, the tape cassette 30 according to the third embodiment is assembled as a so-called thermal type tape cassette. Since the thermal type tape cassette 30 does not need to house other print medium and an ink ribbon, the tape cassette 30 does not include the first tape spool on which the first tape is wound and the ribbon spool on which the ink ribbon is wound.

[0159] In the tape printer 1 and the tape cassette 30 explained above, printing is performed on the heat-sensitive paper tape 55 similar to the first embodiment. However, the heat-sensitive paper tape 55 is pulled out from the second tape spool 41, unlike the first embodiment.

[0160] As shown in FIGS. 8, 9 and 32, the positional relationships among the respective portions provided in the tape cassette 30 according to the third embodiment are similar to those of the first embodiment but are different in the following points. Specifically, the second tape spool 41, on which the heat-sensitive paper tape 55 is wound, is rotatably supported by the second tape support hole 66. For that reason, the center of gravity of the heat-sensitive paper tape 55 is positioned on the division line K in a plan view.

[0161] With the above positional relationships, in the tape cassette 30 according to the third embodiment, the center of gravity of the entire tape cassette 30 is positioned on or in the vicinity of the division line K in a plan view. The user may vertically insert the tape cassette 30 having such a weight distribution in the cassette housing portion 8 while maintaining the top wall 35 and the bottom wall 36 substantially horizontal with the fingers sandwiching the side wall 37 at both the right and left sides. At this time, since the center of gravity of the tape cassette 30 is positioned on or in the vicinity of the division line K, the tape cassette 30 may be prevented from inclining with the division line K as the center of rotation.

[0162] The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 according to the third embodiment are similar to those in the second embodiment (refer to FIGS. 27 and 28). Specifically, the tape cassette 30 is guided to a proper posi-

tion in the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120). Also when the tape cassette 30 is removed from the cassette housing portion 8, the tape cassette 30 is guided upward along the two guide shafts.

[0163] The guide hole 47 according to the third embodiment has a circular opening in a plan view, and its opening width is larger than the diameter of the small-diameter shaft portion 120B of the guide shaft 120. For that reason, similar to the first embodiment, the corresponding holes (the roller support hole 64 and the guide hole 47) of the tape cassette 30 do not need to be accurately positioned with respect to all the two guide shafts (the tape drive shaft 100 and the guide shaft 120) provided in the cassette housing portion 8. Therefore, the user's load may be reduced at the installation of the tape cassette 30. The diameter of the guide hole 47 according to the third embodiment is substantially equal to the diameter of the large-diameter shaft portion 120A of the guide shaft 120. For that reason, when the guide shaft 120 is inserted in the guide hole 47, the large-diameter shaft portion 120A is tightly engaged in all the circumferential directions of the guide hole 47. Therefore, the tape cassette 30 installed in the cassette housing portion 8 may be more accurately positioned at a proper horizontal position.

[0164] The tape cassette 30 according to the third embodiment has a weight distribution such that the center of gravity of the tape cassette 30 is on or in the vicinity of the division line K in a plan view. For that reason, an inclination due to the own weight of the tape cassette 30 may be less likely to occur in the process of the installation of the tape cassette 30 in the cassette housing portion 8. Thus, even when the auxiliary shaft 110 is not provided unlike the first embodiment, the tape cassette 30 may be guided to the proper position in the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120).

[0165] Further, the tape cassette 30 is guided in the vertical direction at the two points, that is, a pair of corner portions on a diagonal of the tape cassette 30 (specifically, the roller support hole 64 and the guide hole 47) in a plan view. In other words, the tape cassette 30 is guided in the installation/removal direction about the division line K that passes through or in the vicinity of the center of gravity of the heat-sensitive paper tape 55. For that reason, a positional displacement or an inclination may be appropriately prevented when the tape cassette 30 is installed in the cassette housing portion 8.

[0166] In the third embodiment, the thermal type tape cassette 30 formed from a general purpose cassette is used in the general purpose tape printer 1. However, a dedicated tape cassette for the thermal type may be configured, or the tape cassette 30 of the third embodiment may be used in a dedicated tape printer for the thermal type.

[0167] For example, as shown in FIGS. 19 and 34, a tape printer 1 dedicated for the thermal type may be con-

figured. An ink ribbon is not used for printing on the print medium with the thermal type. Therefore, as described above with reference to FIG. 19, the tape printer 1 dedicated for the thermal type does not include the ribbon take-up shaft 95. Further, the tape printer 1 shown in FIG. 34 does not include the auxiliary shaft 110 unlike the tape printer 1 shown in FIG. 19 (refer to FIG. 34).

[0168] As shown in FIGS. 33 and 34, a dedicated tape cassette 30 for the thermal type capable of housing only the heat-sensitive paper tape may be configured. Unlike the tape cassette 30 dedicated for the thermal type shown in FIGS. 20 and 21, the tape cassette 30 dedicated for the thermal type shown in FIGS. 33 and 34 is configured to house the heat-sensitive paper tape 55 on the division line K. For that reason, the tape cassette 30 shown in FIGS. 33 and 34 has none of the first tape spool and the first tape support hole 65 for supporting the first tape spool, the ribbon take-up spool 44 and the take-up spool support hole 67 for supporting the ribbon take-up spool 44, and the ribbon spool and the ribbon support hole 68 for supporting the ribbon spool.

[0169] Also with such a configuration, the tape cassette 30 may be installed in and removed from the tape printer 1 in a similar manner as above. In other words, as shown in FIG. 35, the two guide shafts (the tape drive shaft 100 and the guide shaft 120) are inserted in the two corresponding guide holes (the roller support hole 64 and the guide hole 47), respectively, so that the tape cassette 30 is guided to the proper position in the cassette housing portion 8.

<Fourth embodiment>

[0170] The tape printer 1 and the tape cassette 30 according to a fourth embodiment will be explained with reference to FIGS. 36 and 37. The fourth embodiment describes an example in which the tape cassette 30 houses two tapes (specifically, a double-sided adhesive tape and a film tape as a print medium tape) and an ink ribbon, and has two guide holes for guiding the tape cassette 30 when the tape cassette 30 is installed in or removed from the tape printer 1. The fourth embodiment also describes an example in which the tape printer 1 has two guide shafts for guiding the tape cassette 30 to a proper position corresponding to the two guide holes described above.

[0171] As shown in FIGS. 36 and 37, the tape printer 1 according to the fourth embodiment is a general purpose device that can commonly use a plurality of tape cassettes 30 with various tape types, similar to the tape printer 1 according to the second embodiment (refer to FIGS. 24 to 26). Unlike the first embodiment, the tape printer 1 according to the fourth embodiment is not provided with the auxiliary shaft 110.

[0172] The tape cassette 30 according to the fourth embodiment is a general purpose cassette that can be assembled as various types, similar to the tape cassette 30 according to the first embodiment (refer to FIGS. 3 and 7 to 13). As shown in FIGS. 36 and 37, in the tape

cassette 30 according to the fourth embodiment, the first tape spool 40 is rotatably supported by the first tape support hole 65, and a double-sided adhesive tape 58 as a first tape is wound on the first tape spool 40. The second tape spool 41 is rotatably supported by the second tape support hole 66, and a film tape 59 as a second tape is wound on the second tape spool 41. The ribbon spool 42 is rotatably supported by the ribbon support hole 68, and the ink ribbon 60 is wound on the ribbon spool 42. In other words, the tape cassette 30 according to the fourth embodiment is assembled as a so-called laminated type tape cassette.

[0173] In the tape printer 1 and the tape cassette 30 according to the fourth embodiment, when printing is performed in the tape printer 1, the tape feed roller 46 that is driven to rotate via the tape drive shaft 100 pulls out the film tape 59 from the second tape spool 41 in concert with the movable feed roller 14. Further, the ribbon take-up spool 44, which is driven to rotate via the ribbon take-up shaft 95, pulls out the unused ink ribbon 60 from the ribbon spool 42 in synchronization with the print speed.

[0174] The film tape 59 that has been pulled out from the second tape spool 41 passes the right side of the ribbon support hole 68 to be fed along the feed path within the arm portion 34. Further, the film tape 59 is supplied from the exit 34A to the head insertion portion 39 in a state in which the ink ribbon 60 is joined to the surface of the film tape 59. The film tape 59 and the ink ribbon 60 are fed between the thermal head 10 and the platen roller 15 of the tape printer 1. Then, characters are printed onto the print surface of the film tape 59 by the thermal head 10. Thereafter, the used ink ribbon 60 is peeled off from the printed film tape 59 at the guide wall 38, and is wound onto the ribbon take-up spool 44.

[0175] Meanwhile, the double-sided adhesive tape 58 is pulled out from the first tape spool 40 in concert with the tape feed roller 46 and the movable feed roller 14. While being guided and caught between the tape feed roller 46 and the movable feed roller 14, the double-sided adhesive tape 58 is layered onto and affixed to the print surface of the printed film tape 59. The printed film tape 59 to which the double-sided adhesive tape 58 has been affixed (that is, the printed tape 50) is further fed toward the tape discharge aperture 49, discharged from the discharge aperture 49, and cut by the cutting mechanism 17.

[0176] As shown in FIGS. 8, 9 and 36, the positional relationships among the respective portions provided in the tape cassette 30 according to the fourth embodiment are similar to the first embodiment, but are different in the following points. Specifically, the first tape spool 40 on which the double-sided adhesive tape 58 is wound is rotatably supported by the first tape support hole 65. For that reason, the center of gravity of the double-sided adhesive tape 58 is positioned within the first housing area 30C in a plan view.

[0177] On the other hand, the ribbon spool 42 on which the unused ink ribbon 60 is wound is rotatably supported by the ribbon support hole 68. The ribbon take-up spool

44 on which the used ink ribbon 60 is wound is rotatably supported by the take-up spool support hole 67. For that reason, the center of gravity of the ink ribbon 60 is positioned within the second housing area 30D in a plan view. The second tape spool 41 on which the film tape 59 is wound is rotatably supported by the second tape support hole 66. For that reason, the center of gravity of the film tape 59 is positioned on the division line K in a plan view.

[0178] With the above positional relationships, in the tape cassette 30 according to the fourth embodiment, the weights of the first housing area 30C and the second housing area 30D defined by the division line K are close to each other. Further, the center of gravity of the entire tape cassette 30 is positioned on or in the vicinity of the division line K in a plan view. The user may vertically insert the tape cassette 30 having such a weight distribution in the cassette housing portion 8 while maintaining the top wall 35 and the bottom wall 36 substantially horizontal with the fingers sandwiching the side wall 37 at both the right and left sides.

[0179] At this time, since a weight imbalance in the tape cassette 30 is little, and additionally the center of gravity of the tape cassette 30 is positioned on or in the vicinity of the division line K, the tape cassette 30 may be prevented from inclining with the division line K as the center of rotation. Further, although the double-sided adhesive tape 58 is generally heavier than the ink ribbon 60, the difference in weight between the first housing area 30C and the second housing area 30D becomes much smaller due to the weight of the ribbon take-up spool 44 (that is, the weight imbalance of the tape cassette 30 can be reduced with the ribbon take-up spool 44).

[0180] The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 according to the fourth embodiment is similar to the second embodiment (refer to FIG. 27 and 28). Specifically, as shown in FIG. 37, the tape cassette 30 is guided to a proper position in the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120). Also when the tape cassette 30 is removed from the cassette housing portion 8, the tape cassette 30 is guided upward along the two guide shafts.

[0181] The guide hole 47 according to the fourth embodiment has a substantially rectangular opening with rounded four corners in a plan view. The opening width of the guide hole 47 in the left-right direction is larger than the opening width in the front-rear direction in a plan view. The both opening widths of the guide hole 47 in the front-rear direction and the left-right direction are larger than the diameter of the small-diameter shaft portion 120B of the guide shaft 120. The opening width in the left-right direction is larger than the opening width in the front-rear direction. The opening width of the guide hole 47 in the front-rear direction is substantially equal to the diameter of the large-diameter shaft portion 120A of the guide shaft 120. Therefore, the guide shaft 120 is inserted with the large-diameter shaft portion 120A to be tightly engaged in the front-rear direction and looseness is allowed in the

left-right direction of the large-diameter shaft portion 120A.

[0182] Thus, similar to the first embodiment, the corresponding holes (the roller support hole 64 and the guide hole 47) of the tape cassette 30 do not need to be accurately positioned with respect to all the two guide shafts (the tape drive shaft 100 and the guide shaft 120) provided in the cassette housing portion 8. Therefore, the user's load may be reduced at the installation of the tape cassette 30. Further, the tape cassette 30 can be smoothly installed and removed while maintaining the print quality.

[0183] The tape cassette 30 according to the fourth embodiment has a weight distribution such that the weights of the first housing area 30C and the second housing area 30D are close to each other, and the center of gravity of the tape cassette 30 is positioned on or in the vicinity of the division line K in a plan view. For that reason, an inclination due to the own weight of the tape cassette 30 may be less likely to occur in the process of the installation of the tape cassette 30 in the cassette housing portion 8. Thus, even when the auxiliary shaft 110 is not provided, unlike the first embodiment, the tape cassette 30 may be guided to the proper position of the cassette housing portion 8 by the two guide shafts (the tape drive shaft 100 and the guide shaft 120).

[0184] Further, the tape cassette 30 is guided in the vertical direction at two points, that is, a pair of corner portions (specifically, the roller support hole 64 and the guide hole 47) on the diagonal of the tape cassette 30 in a plan view. In other words, the tape cassette 30 is guided in the installation/removal direction about the division line K that passes between the center of gravity of the double-sided adhesive tape 58 and the center of gravity of the ink ribbon 60 and that passes through or in the vicinity of the center of gravity of the film tape 59. For that reason, a positional displacement or an inclination may be appropriately prevented when the tape cassette 30 is installed in the cassette housing portion 8.

[0185] In the fourth embodiment, the laminated type tape cassette 30 formed from a general purpose cassette is used in the tape printer 1 including the two guide shafts. However, the tape cassette 30 according to the fourth embodiment may be installed in the tape printer 1 including the three guide shafts according to the first embodiment, for example. In this case, similar to the first embodiment, the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120) are inserted in the three corresponding guide holes (the roller support hole 64, the first tape support hole 65 and the guide hole 47), respectively, so that the tape cassette 30 is guided to the proper position in the cassette housing portion 8 (refer to FIGS. 14 to 16).

<Common elements in first to fourth embodiments>

[0186] In the first to fourth embodiments described above, the examples in which the present invention is

applied to various types of tape cassettes 30 and tape printers 1 have been individually explained. The elements commonly employed in the tape cassettes 30 and the tape printers 1 exemplified in the first to fourth embodiments are explained below.

[0187] Each of the tape cassettes 30 according to the first to fourth embodiment includes a box-shaped housing (the cassette case 31) having a generally rectangular shape. The cassette case 31 includes the top wall 35, the bottom wall 36, and the side wall 37 which define the periphery of the cassette case 31. In the interior of the cassette case 31, at least one tape (at least one of the heat-sensitive paper tape 55, the print tape 57, the double-sided adhesive tape 58 and the film tape) is supported in a tape containing area defined within the periphery. A pair of cavities (the roller support hole 64 and the guide hole 47) extending from the bottom wall 36 is provided between the tape containing area and the periphery at opposite ends of a diagonal connecting a first corner portion (the front left corner portion) and a second corner portion (the rear right corner portion) of the cassette case 31.

[0188] The tape printer 1 according to the first to fourth embodiments includes at least two guide shafts (the tape drive shaft 100 and the guide shaft 120) that can be inserted in the pair of cavities (the roller support hole 64 and the guide hole 47), respectively, and that guide the tape cassette 30 in the installation/removal direction when the tape cassette 30 is installed in the tape printer 1.

[0189] Due to the common elements described above, the first to fourth embodiments have the common effect in which the tape cassette 30 may be more accurately and smoothly installed in and removed from the tape printer 1 along the two guide shafts to be inserted in the pair of cavities, respectively, regardless of the influence of a heavy tape housed in the tape containing area or the weight distribution of the tape cassette 30. In addition, as described above, the individual configuration and effect may be obtained for each embodiment based on the above common elements and their effects in the first to fourth embodiments.

[0190] In the above-described embodiments, the cassette case 31 corresponds to a housing of the present invention. The roller support hole 64 and the guide hole 47 correspond to a pair of cavities of the present invention. The print tape 57 wound on the first tape spool 40 in the second embodiment and the double-sided adhesive tape 58 wound on the first tape spool 40 in the fourth embodiment do not correspond to a tape of the present invention. The ink ribbon 60 wound on the ribbon spool 42 in the second and fourth embodiments corresponds to an ink ribbon of the present invention. The first housing area 30C corresponds to a first area, and the second housing area 30D corresponds to a second area of the present invention. The tape feed motor 23 corresponds to a tape feeding device of the present invention. The thermal head 10 corresponds to a printing device of the present invention. The tape drive shaft 100 corresponds

to a first guide shaft, and the guide shaft 120 corresponds to a second guide shaft of the present invention.

[0191] The present invention is not limited to the first to fourth embodiments described above, and can be modified variously. The tape printer 1 and the tape cassette 30 may be configured to have a combination of various features described in the first to fourth embodiments, for example. Modified embodiments of the tape printer 1 and the tape cassette 30 based on the above embodiments will be explained below.

[0192] For example, in the above-described embodiments, the cassette housing portion 8 is configured as a housing portion that has a rectangular opening that generally corresponds to the plan shape of the tape cassette 30. However, the cassette housing portion 8 may have a different shape. For example, the cassette support portion 8B that supports the common portion 32 from below may not be provided. Specifically, as shown in a first modified embodiment illustrated in FIGS. 38 and 39, the cassette housing portion 8 may be configured as a planar portion that is larger in a plan view than the plan shape of the tape cassette 30.

[0193] In the first modified embodiment, as shown in FIG. 40, the tape drive shaft 100, the guide shaft 120, the auxiliary shaft 110, the ribbon take-up shaft 95, the positioning pins 102, 103 and the head holder 74 are standing upward from the same height position on the cassette housing portion 8 (in other words, standing upward from the common plane surface). The positional relationships among these members and the height relationships among their upper ends are similar to those in the first embodiment. The positioning pins 102, 103 and the guide shaft 120 in the first modified embodiment are longer than those in the first embodiment by the height of the cassette support portion 8B.

[0194] The installation/removal modes of the tape cassette 30 in the first modified embodiment are similar to those of the first embodiment. Specifically, the tape cassette 30 is guided to a proper position in the cassette housing portion 8 by the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120). Then, the tape cassette 30 is positioned at a proper horizontal position by the guide shaft 120 and the positioning pin 102, and is positioned at a proper height position by the positioning pins 102 and 103. In other words, the proper position in the cassette housing portion 8 is defined by the guide shaft 120 and the positioning pins 102, 103. For that reason, even when the plan shape of the cassette housing portion 8 does not correspond to the plan shape of the tape cassette 30, the tape cassette 30 can be positioned at the proper position.

[0195] As described above, it may be preferable that the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are respectively inserted at the same time in the openings 64B, 65B and 47B of the tape cassette 30 to be installed in the cassette housing portion 8. As shown in FIG. 40, in the tape cassette 30 having a large tape width (such as 36 mm), the common portion

32 forms a step in the thickness direction (that is, in the vertical direction). For that reason, the upper end of the guide shaft 120 to be inserted in the opening 47B formed at the lower surface of the common portion 32 is at the higher position than the tape drive shaft 100 and the auxiliary shaft 110 by the height of the step formed by the common portion 32. In other words, the height positions of the respective upper ends of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 may be defined by the height positions of the openings 64B, 65B and 47B of the tape cassette 30 to be installed in the cassette housing portion 8.

[0196] As shown in FIG. 41, in the tape cassette 30 having a small tape width (such as 12 mm), the common portion 32 does not form a step in the thickness direction (that is, in vertical direction). Therefore, the height positions of the openings 64B, 65B and 47B are substantially the same. For that reason, in the tape printer 1 in which the tape cassette 30 having a small tape width is used, the height positions of the upper ends of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 may preferably be set to be substantially the same. In other words, it may be preferable that the height positions of the respective upper ends of the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are changed depending on the height positions of the openings 64B, 65B and 47B of the tape cassette 30 to be installed in the cassette housing portion 8. Thus, the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120) may be inserted in the three guide holes (the roller support hole 64, the guide hole 47 and the first tape support hole 65) at the same time, respectively, depending on the thickness (the length in the vertical direction) of the tape cassette 30.

[0197] Further, the guide shaft 120 may extend to a higher position (for example, the length of the guide shaft 120 may be made larger) corresponding to the tape cassette 30 having a larger tape width (such as 48 mm). However, the length of the guide shaft 120 may be restricted depending on the shape or size of the tape printer 1 (particularly, the cassette housing portion 8). In such a case, when the tape cassette 30 is installed in the cassette housing portion 8, at first, the two guide shafts (the tape drive shaft 100 and the auxiliary shaft 110) may be inserted in the two guide holes (the roller support hole 64 and the first tape support hole 65). Then, the third guide shaft (the guide shaft 120) may be inserted in the third guide hole (the guide hole 47) while the tape cassette 30 is being guided by the two guide shafts and moved down. According to this installation mode, before the guide shaft 120 is inserted in the guide hole 47, the head holder 74 and the ribbon take-up shaft 95 may be inserted in the head insertion portion 39 and the take-up spool support hole 67, respectively.

[0198] As described above, the head insertion portion 39 and the take-up spool support hole 67 each have an opening width through which the head holder 74 and the ribbon take-up shaft 95 are loosely inserted, respectively.

For that reason, a failure in which the head holder 74 or the ribbon take-up shaft 95 contacts other members to hinder the installation of the tape cassette 30 may be prevented in the process of the installation of the tape cassette 30. Furthermore, even if a positional displacement or an inclination occurs when the head holder 74 is inserted in the head insertion portion 39 while the tape cassette 30 is being guided by the two guide shafts, when the guide shaft 120 is inserted in the guide hole 47, the head holder 74 is corrected to a proper installation state. This also applies to the take-up spool support hole 67 and the ribbon take-up shaft 95. Thus, even when the upper end position of the guide shaft 120 is restricted, the tape cassette 30 may be guided to and positioned at a proper position in the cassette housing portion 8.

[0199] Moreover, even when the tape drive shaft 100 and the auxiliary shaft 110 are equal to or lower than the head holder 74 and the ribbon take-up shaft 95, and the guide shaft 120 does not enter the guide hole 47 at the start of the installation of the tape cassette 30, similar effects as the above embodiments may be obtained. An example will be given below in which the head holder 74 and the ribbon take-up shaft 95 are inserted in the head insertion portion 39 and the take-up spool support hole 67, respectively, before the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are inserted in the roller support hole 64, the first tape support hole 65, and the guide hole 47, respectively, in the process of the installation of the tape cassette 30 in the cassette housing portion 8.

[0200] In this case, since the tape cassette 30 has not been guided by any of the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120) when the head holder 74 and the ribbon take-up shaft 95 are inserted in the head insertion portion 39 and the take-up spool support hole 67, respectively, the tape cassette 30 may be displaced or inclined as described above. However, when the tape cassette 30 is further moved down, the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120 are inserted in the first tape support hole 65, the roller support hole 64 and the guide hole 47, respectively. Then, the tape cassette 30 may be corrected to a proper installation state. Thereafter, the tape cassette 30 can be smoothly installed toward the proper position in the cassette housing portion 8 along the three guide shafts.

[0201] Further, the tape cassette 30 can be smoothly removed along the three guide shafts from the beginning. In this manner, even when the upper end positions of all the three guide shafts are restricted, the tape cassette 30 may be guided to and positioned at the proper position in the cassette housing portion 8.

[0202] The height position of the tape cassette 30 installed in the cassette housing portion 8 may not be defined by the positioning pins 102 and 103, unlike the above-described embodiments. Specifically, as shown in a second modified embodiment illustrated in FIG. 42, the positioning pin 103 may not be provided in the cas-

sette housing portion 8. In this case, as shown in FIG. 43, the guide hole 47 does not have the opening 47A that passes through the top wall 35 of the tape cassette 30, and the upper end of the guide hole 47 is closed by a ceiling wall portion 47D. FIG. 43 is a partly cross sectional view around the guide hole 47 and its vicinity as seen from the right side of the tape cassette 30.

[0203] Even with such a configuration, the installation/removal modes of the tape cassette 30 are similar to those in the first embodiments. Specifically, the tape cassette 30 is guided to a proper position in the cassette housing portion 8 by the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120). Then, the tape cassette 30 is positioned at a proper horizontal position by the guide shaft 120 and the positioning pin 102. The upper end of the guide shaft 120 inserted in the guide hole 47 contacts the ceiling wall portion 47D at the rear right corner portion of a tape cassette 30, so that the tape cassette 30 may be positioned at a proper height position. Such a tape cassette 30 is not covered by the claims. Moreover, the tape cassette 30 is positioned at the proper height position by the positioning pin 102 inserted in the pin hole 53 at the left side end of the tape cassette 30 in a similar manner as in the first embodiments.

[0204] As described above, the guide shaft 120 is provided adjacent to the positioning pin 103. For that reason, with the configuration in which the upper end of the guide shaft 120 is engaged within the guide hole 47, the guide shaft 120 may also serve to position the tape cassette 30 in the height direction, instead of the positioning pin 103. In this manner, the guide shaft 120 may be utilized as one of positioning members in the height direction so that the positioning pin 103 may not need to be additionally provided, thereby simplifying the configuration of the tape printer 1. If the height position of the tape cassette 30 is not positioned by the common portion 32, as in the above-described second modified embodiment, the cassette case 31 of the tape cassette 30 may not have the common portion 32, as shown in FIG. 42.

[0205] Although the first and second modified embodiments (refer to FIGS. 38 to 43) describe examples in which the tape cassette 30 is guided by the three guide shafts, the tape cassette 30 may be guided by the two guide shafts (the tape drive shaft 100 and the guide shaft 120). Specifically, as shown in a third modified embodiment illustrated in FIG. 44, even when the auxiliary shaft 110 is not provided in the cassette housing portion 8, the cassette housing portion 8 may be configured as a planar portion that is larger than the plan shape of the tape cassette 30.

[0206] In addition, the height positions of the respective upper ends of the tape drive shaft 100 and the guide shaft 120 may be changed depending on the height positions of the openings 64B and 47B of the tape cassette 30 to be installed in the cassette housing portion 8. Further, the guide shaft 120 may position the tape cassette 30 in the height direction, instead of the positioning pin 103.

The tape cassette 30 may not be provided with the first tape support hole 65, similar to the example shown in FIG. 29. In other words, the cylindrical wall portion 65D that rotatably supports the first tape spool 40 within the cassette case 31 may be provided between the top wall 35 and the bottom wall 36, instead of the first tape support hole 65.

[0207] Further, in the above-described embodiments, the tape cassette 30 are formed from a general purpose cassette and assembled as the thermal type, receptor type or laminated type. However, the types of the tape cassette 30 are not limited to these examples. For example, as shown in a fourth modified embodiment illustrated in FIG. 45, the tape cassette 30 may be assembled as a so-called heat-sensitive laminated type tape cassette. In the heat-sensitive laminated type cassette, the first tape spool 40, on which the double-sided adhesive tape 58 as the first tape is wound, is rotatably supported by the first tape support hole 65. The second tape spool 41, on which the heat-sensitive paper tape 55 as the second tape is wound, is rotatably supported by the second tape support hole 66. Since an ink ribbon is not used in a so-called heat-sensitive laminated type tape cassette, a ribbon spool is not provided.

[0208] The tape printer 1 in which the tape cassette shown in FIG. 45 is used may be similar to the tape printer 1 in the first embodiment. When printing is performed in the tape printer 1, the tape feed roller 46 that is driven to rotate via the tape drive shaft 100 pulls out the heat-sensitive paper tape 55 from the second tape spool 41 in concert with the movable feed roller 14. The heat-sensitive paper tape 55 that has been pulled out from the second tape spool 41 passes the right side of the ribbon support hole 68 to be fed along the feed path within the arm portion 34. Further, the heat-sensitive paper tape 55 is supplied from the exit 34A of the arm portion 34 to the head insertion portion 39, and fed between the thermal head 10 and the platen roller 15. Then, characters are printed on the print surface of the print tape 57 by the thermal head 10.

[0209] Meanwhile, the double-sided adhesive tape 58 is pulled out from the first tape spool 40 by the tape feed roller 46 in concert with the movable feed roller 14. When being guided and caught between the tape feed roller 46 and the movable feed roller 14, the double-sided adhesive tape 58 is layered onto and affixed to the print surface of the printed heat-sensitive paper tape 55. The printed heat-sensitive paper tape 55 to which the double-sided adhesive tape 58 has been affixed (that is, the printed tape 50) is further fed toward the tape discharge aperture 49, discharged from the discharge aperture 49, and cut by the cutting mechanism 17.

[0210] The positional relationships among the respective portions provided in the tape cassette 30 shown in FIG. 45 are similar to those in the first embodiment, but are different in the following points. Specifically, the center of gravity of the double-sided adhesive tape 58 wound on the first tape spool 40 is positioned within the first

housing area 30C in a plan view. The center of gravity of the heat-sensitive paper tape 55 wound on the second tape spool 41 is positioned on the division line K in a plan view. With such positional relationships, in the tape cassette 30 shown in FIG. 45, the first housing area 30C in which the center of gravity of the double-sided adhesive tape 58 is positioned is heavier relative to the second housing area 30D. Therefore, the first housing area 30C may be inclined downward with the division line K as the center of rotation due to a weight imbalance of the tape cassette 30.

[0211] The installation/removal modes of the tape cassette 30 with respect to the cassette housing portion 8 shown in FIG. 45 are similar to those in the first embodiment (refer to FIGS. 14 to 16). Specifically, the tape cassette 30 is guided to a proper position in the cassette housing portion 8 by the three guide shafts (the tape drive shaft 100, the auxiliary shaft 110 and the guide shaft 120). When the tape cassette 30 is removed from the cassette housing portion 8, the tape cassette 30 is guided upward along the three guide shafts. In the fourth modified embodiment, however, the tape cassette 30 may be guided by the two guide shafts (the tape drive shaft 100 and the guide shaft 120).

[0212] Similar to the first embodiment, it may be preferable that the center of gravity of the entire tape cassette 30 is positioned within the area defined by connecting the roller support hole 64, the first tape support hole 65 and the guide hole 47 in a plan view. Since the center of gravity of the heat-sensitive paper tape 55 is positioned on the division line K in the tape cassette 30 shown in FIG. 45, the center of gravity of the tape cassette 30 is closer to the division line K than a tape cassette in which the heat-sensitive paper tape 55 is not mounted at this position. For that reason, the tape cassette 30 shown in FIG. 45 has a weight distribution such that the center of gravity of the tape cassette may be positioned within the area defined by connecting the roller support hole 64, the first tape support hole 65 and the guide hole 47 in a plan view.

[0213] The guide hole 47 shown in FIG. 45 is an ellipse-shaped hole similar to the guide hole 47 in the second embodiment (refer to FIG. 24 and the like). However, the guide hole 47 shown in FIG. 45 is different in that the guide hole 47 has the major axis along the division line K and the minor axis along a direction perpendicular to the division line K in a plan view. With the guide hole 47 shown in FIG. 45, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the division line K. Therefore, a load of the user in positioning the tape cassette 30 may be reduced. In this manner, the guide hole 47 may be configured to have an arbitrary opening shape such as a circular hole, an ellipse-shaped hole or an elongated hole.

[0214] For example, a modified embodiment of the guide hole 47 shown in FIG. 46 is an elongated hole similar to the guide hole 47 in the first embodiment (refer to FIG. 8 and the like), but is different in that the guide

hole 47 shown in FIG. 46 has the long sides extending in the front-rear direction and the short sides extending in the left-right direction in a plan view. With this guide hole 47, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the front-rear direction. Therefore, a load of the user in positioning the tape cassette 30 may be reduced. FIG. 46 exemplifies the case in which the guide hole 47 is an elongated hole, but the guide hole 47 may be configured as an ellipse-shaped hole having the major axis in the front-rear direction.

[0215] Another modified guide hole 47 shown in FIG. 47 is an elongated hole similar to the first embodiment (refer to FIG. 8 and the like), but is different in that the guide hole 47 shown in FIG. 47 has the long sides extending parallel to the division line K and the short sides extending perpendicular to the division line K. With this guide hole 47, similar to the guide hole 47 shown in FIG. 45, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the division line K. Therefore, a load of the user in positioning the tape cassette 30 may be reduced.

[0216] In addition, yet another modified embodiment of the guide hole 47 shown in FIG. 48 is an elongated hole similar to the first embodiment (refer to FIG. 8 and the like), but is different in that the guide hole 47 shown in FIG. 48 has the long sides extending perpendicular to the division line K and the short sides extending parallel to the division line K. With this guide hole 47, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the direction perpendicular to the division line K. Therefore, a load of the user in positioning the tape cassette 30 may be reduced. FIG. 48 exemplifies the case in which the guide hole 47 is an elongated hole, but the guide hole 47 may be configured as an ellipse-shaped hole that has the major axis perpendicular to the division line K.

[0217] In addition, yet another modified embodiment of the guide hole 47 shown in FIGS. 49 and 50 is a groove that is formed in the side wall 37 that forms the right side surface of the tape cassette 30. The groove is concaved toward the left direction in a plan view over the entire height (between the top wall 35 and the lower surface of the common portion 32 at the rear right portion) at the rear right portion of the cassette case 31, and has a U-shaped cross section. The opening width of the U-grooved guide hole 47 is larger than the diameter of the small-diameter shaft portion 120B and substantially equal to the diameter of the large-diameter shaft portion 120A. In this case, when the tape cassette 30 is installed in the cassette housing portion 8, the guide shaft 120 is inserted in the U-grooved guide hole 47 from below and the tape cassette 30 is guided downward along the standing direction of the guide shaft 120 similar to the case in which the guide hole 47 is a through-hole or an indentation. Then, when the large-diameter shaft portion 120A is fitted in the guide hole 47, the tape cassette 30 is positioned.

[0218] In the U-grooved guide hole 47 shown in FIGS. 49 and 50, the user's load may be reduced at the installation of the tape cassette 30, and the tape cassette 30 may be smoothly installed and removed similar to the horizontally-long guide hole 47 exemplified in the first embodiment (refer to FIG. 8 and the like). The guide shaft 120 inserted in the U-grooved guide hole 47 is exposed such that it can be seen from the right side of the tape cassette 30. Therefore, the user can see the guide shaft 120 inserted in the guide hole 47 and check the state of the tape cassette 30 being installed or removed with respect to the cassette housing portion 8.

[0219] The U-grooved guide hole 47 shown in FIGS. 49 and 50 may be modified to an arbitrary groove shape. For example, another modified embodiment of the guide hole 47 shown in FIG. 51 is a groove formed in the side wall 37 that forms the rear surface of the tape cassette 30 and is concaved toward the front direction in a plan view. In this case, similar to the guide hole 47 shown in FIG. 46, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the front-rear direction.

[0220] Another modified embodiment of the guide hole 47 shown in FIG. 52 is a groove formed in the side wall 37 that forms the right side surface of the tape cassette 30 and is concaved along the division line K in a plan view. In this case, similar to the guide hole 47 shown in FIG. 47, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the division line K. Yet another modified embodiment of the guide hole 47 shown in FIG. 53 is a groove formed in the side wall 37 that forms the rear surface of the tape cassette 30 and is concaved along the direction perpendicular to the division line K in a plan view. In this case, similar to the guide hole 47 shown in FIG. 48, allowance for the horizontal positioning accuracy of the guide shaft 120 may be made larger along the direction perpendicular to the division line K.

[0221] In addition, another modified guide hole 47, which is not covered by the claims and shown in FIGS. 54 and 55, is a groove that is formed in the side wall 37 that forms the right side surface of the tape cassette 30 and in the bottom wall 36, and forms a U-shaped cross section concaved toward the left direction in a plan view. The U-grooved guide hole 47 extends from the bottom wall 36 to the portion slightly down from the top wall 35 at the rear right portion of the cassette case 31. The upper end of the groove is closed by a ceiling wall portion 47E. In other words, the guide hole 47 does not open upward in the top wall 35. The width of the U-shaped cross section of the guide hole 47 is larger than the diameter of the small-diameter shaft portion 120B and is substantially equal to the diameter of the large-diameter shaft portion 120A.

[0222] In this case, when the tape cassette 30 is installed in the cassette housing portion 8, the guide shaft 120 is inserted in the U-grooved guide hole 47 from below and the tape cassette 30 is guided downward along the

standing direction of the guide shaft 120, similar to the case in which the guide hole 47 is a through-hole or an indentation. Then, when the large-diameter shaft portion 120A is fitted in the guide hole 47, the tape cassette 30 is positioned. Particularly, at the right side end of the tape cassette 30, the upper end of the guide shaft 120 inserted in the guide hole 47 contacts the ceiling wall portion 47E, so that the tape cassette 30 is positioned at a proper height position.

[0223] In the guide hole 47 shown in FIGS. 54 and 55, similar to the U-grooved guide hole 47 shown in FIGS. 49 and 50, the user's load may be reduced at the installation of the tape cassette 30, and the tape cassette 30 may be smoothly installed and removed. In addition, the user can see the guide shaft 120 inserted in the guide hole 47 and check the states of the tape cassette 30 being installed in or removed with respect to the cassette housing portion 8. Further, since the guide shaft 120 is utilized as one of positioning members in the height direction, the positioning pin 103 may not need to be additionally provided, thereby simplifying the configuration of the tape printer 1.

[0224] In the first embodiment, the first tape spool 40 is rotatably supported by the cylindrical wall portion 85 that extends through the shaft hole 40D of the first tape spool 40, and the auxiliary shaft 110 that is inserted in and removed from the first tape support hole 65 is also inserted in and removed from the shaft hole 40D at the installation and removal of the tape cassette 30. However, as shown in FIG. 56, in place of the cylindrical wall portion 85, the first tape support hole 65 may be provided with a pair of short cylinders 88. The short cylinders 88 extend from the peripheries of the opening edges of the openings 65A and 65B to the interior of the cassette case 31 toward each other.

[0225] In this case, the first tape spool 40 may have a single-wall configuration in which the heat-sensitive paper tape 55 is wound on the spool main body 40E that is a cylinder member having substantially the same height as the tape width of the print medium (similar to the print tape 57 and the film tape 59). The pair of short cylinders 88 is inserted in the openings at both ends of the spool main body 40E within the cassette case 31. Even with such a configuration, the first tape spool 40 may be rotatably supported by the pair of short cylinders 88 inserted in the shaft hole 40D, and the auxiliary shaft 110 may be inserted in and removed from the first tape support hole 65 at the installation and removal of the tape cassette 30 is also inserted in and removed from the shaft hole 40D.

[0226] The opening 65B of the first tape support hole 65 may be disposed to face the shaft hole 40D such that the auxiliary shaft 110 can be inserted in and removed from the shaft hole 40D of the first tape spool 40 when the tape printer 1 has the auxiliary shaft 110. In other words, the opening 65B provided in the bottom wall 36 and the shaft hole 40D may be connected. In the first embodiment shown in FIG. 10, the opening 65B through which the auxiliary shaft 110 is inserted and removed is

indirectly connected with the shaft hole 40D via the cylindrical wall portion 85, and the shaft hole 65C of the first tape support hole 65 extends through the shaft hole 40D of the first tape spool 40. In the above modified embodiment shown in FIG. 56, the opening 65B through which the auxiliary shaft 110 is inserted and removed is directly connected with the shaft hole 40D via the short cylinder 88, and the shaft hole 65C of the first tape support hole 65 extends through the shaft hole 40D of the first tape spool 40.

[0227] In either case, the opening 65B of the first tape support hole 65 faces the shaft hole 40D of the first tape spool 40 so that the auxiliary shaft 110 that is inserted in and removed from the first tape support hole 65 is also inserted in and removed from the shaft hole 40D. Consequently, the center of gravity of the tape spool 40 on which the heat-sensitive paper tape 55 or the like is wound is guided along the auxiliary shaft 110 at the installation and removal of the tape cassette 30.

[0228] Similar to the first tape support hole 65, the opening 64B of the roller support hole 64 may be disposed to face the shaft hole 46D such that the tape drive shaft 100 can be inserted in and removed from the shaft hole 46D of the tape feed roller 46. In other words, the opening 64B of the roller support hole 64 may be connected with the shaft hole 46D such that the tape drive shaft 100 can also be inserted in and removed from the shaft hole 46D when the tape drive shaft 100 is inserted in and removed from the roller support hole 64.

[0229] In the first to fourth embodiments, various tapes and an ink ribbon (specifically, the heat-sensitive paper tape 55, the print tape 57, the double-sided adhesive tape 58, the film tape 59 and the ink ribbon 60) are wound on the spools (specifically, the first tape spool 40, the second tape spool 41 and the ribbon spool 42), respectively. However, the ink ribbon may not be wound on spools. For example, an ink ribbon may be wound so as to form a hole about the center of winding without the spools to be configured as a so-called, coreless type.

[0230] In the first to fourth embodiments, examples in which the two guide holes (the roller support hole 64 and the guide hole 47) provided in the tape cassette 30 are used so that the tape cassette 30 is guided along the two guide shafts (the tape drive shaft 100 and the guide shaft 120) to be installed in the cassette housing portion 8. However, a member that is inserted in the guide holes of the tape cassette 30 is not limited to the guide shafts provided in the tape printer 1.

[0231] For example, as shown in FIG. 57, a pair of shafts 140 corresponding to the roller support hole 64 and the guide hole 47 may be provided in advance to stand upward at a position where the tape cassette 30 is to be exhibited. Each of the shafts 140 has a shaft 140A and a base 140B. The shaft 140A has a diameter that can be inserted in and removed from the roller support hole 64 and the guide hole 47. The base 140B has a predetermined height, and the shafts 140A are standing upward from the upper surface of the base 140B. When

the tape cassette 30 is exhibited, the user may insert the shafts 140A in the roller support hole 64 and the guide hole 47, respectively. Then, as the tape cassette 30 is moved down along the shafts 140A, the tape cassette 30 is eventually placed on the base 140B positioned at the lower end of the shafts 140A. Thus, the tape cassette 30 may be held by the pair of shafts 140 at a predetermined height position where it can be visually seen with ease.

[0232] If the position of the upper ends of the shafts 140 shown in FIG. 57 may be made higher (for example, the length of each shaft 140A is made larger), a plurality of tape cassettes 30 may be sequentially stacked on the base 140B along the shafts 140A. Thus, the plurality of tape cassettes 30 can be collectively stored, collected, carried and the like. In addition, if one tape cassette 30 is positioned at the upper ends of the shafts 140, the tape cassette 30 can be exhibited at a height position where it can be visually seen with more ease. The usage can be employed by using a set (three) of shafts 140 for the tape cassette 30 provided with the three guide holes (the roller support hole 64, the guide hole 47 and the first tape support hole 65).

Claims

1. A tape cassette (30) comprising:

a generally rectangular box-like housing (31) having a top wall (35), a bottom wall (36), and a side wall (37) defining a periphery of the housing, the side wall including two wall portions disposed adjacent to each other and in mutually orthogonal directions;
a first cavity (64) extending from the bottom wall and disposed between the periphery and a tape containing area defined within the periphery, in the vicinity of or at a first corner portion of the generally rectangular box-like housing;
a second cavity (47) continuously extending upwards from an opening (47B) provided in the bottom wall (36) and disposed between the periphery and the tape containing area, in the vicinity of or at a second corner portion of the housing, the second corner portion being at a diagonal position with respect to the first corner portion in a plan view and being formed by the two wall portions of the side wall; and
a print medium tape (55, 59) wound around a cylindrical tape spool (41) and mounted within the housing (31) in the tape containing area, the tape spool being disposed on a straight line (K) connecting the first cavity (64) and the second cavity (47) **characterized in that**

the second cavity (47) includes an internal wall forming a shaft hole (47C) connecting the opening (47B)

and another opening (47A) provided in the top wall.

2. The tape cassette according to claim 1, wherein the opening provided in the bottom wall is an elongated opening. 5
3. The tape cassette according to claim 2, wherein the elongated opening has a width to allow at least a part of a side portion of a guide shaft (120) to be tightly engaged when the guide shaft (120) is inserted therein, the guide shaft (120) being adapted to guide the tape cassette (30) when the tape cassette is installed in or removed from a tape printer (1). 10
4. The tape cassette according to any one of claims 1 to 3, further comprising: 15
 - a cylindrical tape feed roller (46) that has an insert hole (46D) and an outer peripheral surface (46C) and that is adapted to draw out the print medium tape wound around the tape spool, a part of the outer peripheral surface contacting the print medium tape, 20
 - wherein
 - the first cavity includes a pair of openings provided at positions opposing each other in the top wall and the bottom wall and rotatably supporting the tape feed roller between the top wall and the bottom wall, 25
 - each one of the pair of openings provided in the bottom wall and the top wall includes a cut-out portion that is cut to an outer edge of the bottom wall and of the top wall respectively, and 30
 - the part of the outer peripheral surface contacting the print medium tape protrudes from the bottom wall where the cut-out portion is provided and from the top wall where the cut-out portion is provided. 35
5. The tape cassette according to claim 4, wherein a roller support shaft (100) adapted to rotatably support the tape feed roller (46) is to be fitted in the insert hole (46D) via the first cavity (64). 40
6. The tape cassette according to any one of claims 1 to 5, wherein the second cavity (47) is a groove formed in the side wall (37). 45

Patentansprüche

1. Bandkassette (30), aufweisend: 50

ein allgemein rechtwinkliges, kastenartiges Gehäuse (31) mit einer oberen Wand (35), einer unteren Wand (36) und einer Seitenwand (37), die eine Begrenzung des Gehäuses definieren, wobei die Seitenwand zwei Wandabschnitte be-

inhaltet, die sich nebeneinander in zueinander rechtwinkligen Richtungen befinden;
einen ersten Hohlraum (64), der von der unteren Wand ausgehend und zwischen der Begrenzung und einem Bandaufnahmebereich, der innerhalb der Begrenzung definiert ist, in der Nähe von oder an einem ersten Eckabschnitt des allgemein rechtwinkligen, kastenartigen Gehäuses angeordnet ist;
einen zweiten Hohlraum (47), der von einer Öffnung (47B) ausgehend, die sich in der unteren Wand (36) befindet, kontinuierlich nach oben verläuft und zwischen der Begrenzung und dem Bandaufnahmebereich in der Nähe von oder an einem zweiten Eckabschnitt des Gehäuses angeordnet ist, wobei sich der zweite Eckabschnitt im Verhältnis zu dem ersten Eckabschnitt in einer ebenen Ansicht an einer diagonalen Position befindet und durch die zwei Wandabschnitte der Seitenwand gebildet wird; und
ein bandförmiges Druckmedium (55, 59), das um eine zylindrische Bandspule (41) gewickelt und in dem Gehäuse (31) in dem Bandaufnahmebereich montiert ist, wobei sich die Bandspule auf einer geraden Linie (K) befindet, die den ersten Hohlraum (64) und den zweiten Hohlraum (47) verbindet,
dadurch gekennzeichnet, dass
der zweite Hohlraum (47) eine Innenwand beinhaltet, die ein Stiftloch (47C) bildet, das die Öffnung (47B) und eine weitere Öffnung (47A), die sich in der oberen Wand befindet, verbindet.

2. Bandkassette nach Anspruch 1, wobei die Öffnung, die sich in der unteren Wand befindet, eine längliche Öffnung ist.
3. Bandkassette nach Anspruch 2, wobei die längliche Öffnung eine Breite aufweist, die zumindest einem Teil eines Seitenabschnitts eines Führungsstiftes (120) einen engen Anschluss ermöglicht, wenn der Führungsstift (120) darin eingeführt wird, wobei der Führungsstift (120) dafür ausgelegt ist, die Bandkassette (30) zu führen, wenn die Bandkassette in bzw. aus einem Banddrucker (1) eingebaut oder ausgebaut wird.
4. Bandkassette nach einem der Ansprüche 1 bis 3, ferner aufweisend: 50

eine zylindrische Bandzufuhrwalze (46), die ein Einführloch (46D) und eine äußere periphere Oberfläche (46C) aufweist und die dafür ausgelegt ist, das bandförmige Druckmedium auszuwickeln, das um die Bandspule gewickelt ist, wobei ein Teil der äußeren Begrenzungsoberfläche das bandförmige Druckmedium berührt, wobei

- der erste Hohlraum ein Paar Öffnungen beinhaltet, die sich an Positionen befinden, die einander in der oberen Wand und der unteren Wand gegenüberliegen und die Bandzufuhrwalze zwischen der oberen Wand und der unteren Wand drehbar lagern, jede von dem Paar Öffnungen, die sich in der unteren Wand und der oberen Wand befinden, einen ausgeschnittenen Abschnitt beinhaltet, der bis zu einer Außenkante der unteren Wand bzw. der oberen Wand geschnitten ist, und der Teil der äußeren Begrenzungsoberfläche, der das bandförmige Druckmedium berührt, von der unteren Wand ausgehend, wo sich der ausgeschnittene Abschnitt befindet, bzw. von der oberen Wand ausgehend, wo sich der ausgeschnittene Abschnitt befindet, hervorragt.
5. Bandkassette nach Anspruch 4, wobei eine Walzenlagerwelle (100), die dafür ausgelegt ist, die Bandzufuhrwalze (46) drehbar zu lagern, über den ersten Hohlraum (64) in das Einführloch (46D) eingesetzt ist.
6. Bandkassette nach einem der Ansprüche 1 bis 5, wobei der zweite Hohlraum (47) eine Vertiefung ist, die in der Seitenwand (37) ausgebildet ist.

Revendications

1. Cassette de bande (30) comprenant :

un logement (31) en forme de boîte généralement rectangulaire comportant une paroi supérieure (35), une paroi inférieure (36) et une paroi latérale (37) définissant une périphérie du logement, la paroi latérale incluant deux portions de paroi disposées de manière adjacente l'une à l'autre et dans des directions mutuellement orthogonales ;
une première cavité (64) s'étendant à partir de la paroi inférieure et disposée entre la périphérie et une zone de réception de bande définie dans la périphérie, à proximité de, ou sur une première portion de coin du logement en forme de boîte généralement rectangulaire ;
une seconde cavité (47) s'étendant en continu vers le haut à partir d'une ouverture (47B) prévue dans la paroi inférieure (36) et disposée entre la périphérie et la zone de réception de bande, à proximité de, ou sur une seconde portion de coin du logement, la seconde portion de coin étant sur une position diagonale par rapport à la première portion de coin dans une vue en plan et étant formée par les deux portions de paroi de la paroi latérale ; et
une bande de substrat d'impression (55, 59) en-

roulée autour d'une bobine de bande cylindrique (41) et montée dans le logement (31) dans la zone de réception de bande, la bobine de bande étant disposée sur une ligne droite (K) raccordant la première cavité (64) et la seconde cavité (47),

caractérisée en ce que

la seconde cavité (47) inclut une paroi interne formant un trou d'arbre (47C) raccordant l'ouverture (47B) et une autre ouverture (47A) prévue dans la paroi supérieure.

2. Cassette de bande selon la revendication 1, dans laquelle l'ouverture prévue dans la paroi inférieure est une ouverture allongée.
3. Cassette de bande selon la revendication 2, dans laquelle l'ouverture allongée présente une largeur permettant d'assembler à force au moins une partie d'une portion latérale d'un arbre de guidage (120) lorsque l'arbre de guidage (120) est inséré à l'intérieur, l'arbre de guidage (120) étant adapté afin de guider la cassette de bande (30) lorsque la cassette de bande est installée dans une imprimante de bande (1) ou retirée de cette dernière.
4. Cassette de bande selon l'une quelconque des revendications 1 à 3, comprenant en outre :

un rouleau d'alimentation de bande cylindrique (46) qui présente un orifice d'insertion (46D) et une surface périphérique extérieure (46C) et qui est adapté pour retirer la bande de substrat d'impression enroulée autour de la bobine de bande, une partie de la surface périphérique extérieure touchant la bande de substrat d'impression, dans laquelle
la première cavité inclut une paire d'ouvertures prévues sur des positions s'opposant l'une l'autre dans la paroi supérieure et la paroi inférieure et supportant de manière rotative le rouleau d'alimentation de bande entre la paroi supérieure et la paroi inférieure, chacune de la paire d'ouvertures prévues dans la paroi inférieure et la paroi supérieure inclut une portion découpée qui est coupée sur une arête extérieure de la paroi inférieure et de la paroi supérieure respectivement, et
la partie de la surface périphérique extérieure touchant la bande de substrat d'impression fait saillie de la paroi inférieure où la portion découpée est prévue et de la paroi supérieure où la portion découpée est prévue.

5. Cassette de bande selon la revendication 4, dans laquelle un arbre de support de rouleau (100) adapté pour supporter avec possibilité de rotation le rouleau d'alimentation de bande (46) est destiné à être as-

semblé dans l'orifice d'insertion (46D) à travers la première cavité (64).

6. Cassette de bande selon l'une quelconque des revendications 1 à 5, dans laquelle la seconde cavité (47) est une rainure qui est formée dans la paroi latérale (37).
