Description

Technical Field

- 5 **[0001]** The present invention relates to a compound having a particular chemical structure or a pharmacologically acceptable salt thereof which has an excellent inhibitory effect on EZH1 and/or EZH2 activity.

Background Art

- 10 **[0002]** Chromosomes dynamically control gene replication or transcription by changing their higher-order structures through methylation modification of their constituent DNA and various modifications (acetylation, methylation, phosphorylation, ubiquitination, etc.) of histones (histones H2A, H2B, H3, and H4).

- [0003]** In general, trimethylation of lysine at the fourth position counted from the N-terminus of histone H3 (H3K4me3) functions to activate transcription, whereas trimethylation of lysine at the 27th position (H3K27me3) functions to suppress transcription. The former and latter modifications are performed by a trithorax complex and Polycomb repressive complex 2 (PRC2), respectively (Non Patent Literature 1 and 2).

- [0004]** The Polycomb gene group was identified as a gene controlling the embryogenesis of *Drosophila* and is also conserved in vertebrates (Non Patent Literature 3). In *Drosophila*, the enhancer of zeste protein is a catalytic subunit responsible for the H3K27 methylation modification of PRC2. Both EZH1 (enhancer of zeste homolog 1 (*Drosophila*)) and EZH2 (enhancer of zeste homolog 2 (*Drosophila*)) are mammalian homologs of the *Drosophila* enhancer of zeste (Non Patent Literature 4 and 5). The enzyme activity domains (SET domains) of EZH1 and EZH2 have high homology. In humans or mice, two types of PRC2 exist (PRC2-EZH1 and PRC2-EZH2) which contain EZH1 or EZH2 as a catalytic unit (Non Patent Literature 6 and 7).

- [0005]** In ES cells, EZH1 and EZH2 function cooperatively to participate in maintenance of ES cells (Non Patent Literature 6). EZH1 and EZH2 also act cooperatively on the formation and maintenance of hair follicles and the differentiation of Merkel cells, and both have been reported to also play an important role in maintaining hematopoietic stem cells (Non Patent Literature 8 to 12).

- [0006]** Overexpression of EZH2 has to date been reported in many cancers including prostate cancer, breast cancer, stomach cancer, lung cancer, ovarian cancer, pancreatic cancer, kidney cancer, and head and neck cancer, and the poor prognosis in some of these cancers reportedly correlates with overexpression of EZH2 (Non Patent Literature 13 to 21). There are reports stating that EZH2 knockdown of a cell line derived from such a cancer inhibits cell growth (Non Patent Literature 13 and 22). When EZH2 is overexpressed in an epithelial non-cancer cell line, phenotypes characteristic of cancers appear, such as invasiveness and increased cell growth in a soft agar medium (Non Patent Literature 14).

- [0007]** In follicular lymphoma or follicular center B cell-type diffuse large B-cell lymphoma, somatic mutations have been found in tyrosine 641, alanine 677, and alanine 687 (Y641F, Y641N, Y641S, Y641H, Y641C, A677G, and A687V) of EZH2, and these mutations have been reported to render EZH2 hyperactive to significantly increase intracellular H3K27me3 modification levels (Non Patent Literature 23 to 26). Compounds specifically inhibiting the enzyme activity of EZH2 inhibit, both *in vitro* and *in vivo* (xenograft models), the growth of a cancer cell line having such a somatic mutation in EZH2 (Non Patent Literature 27 and 28 and Patent literature 30).

- [0008]** These facts suggest that knockdown of EZH2 or inhibition of its enzyme activity is useful in the treatment of cancers involving overexpression of EZH2 or a somatic mutation in EZH2.

- [0009]** Although much is known about the malignant transformation of cells containing EZH2, much remains to be analyzed on the relation of EZH1 to the malignant transformation of cells. However, it has recently been found that general inhibition of PRC2 suppresses the progression of acute myeloid leukemia caused by MLL-AF9 fusion gene, whereas inhibition of EZH2 alone is not sufficient for this suppression (Non Patent Literature 29). This means that inhibition of PRC2-EZH2 alone is insufficient for suppressing acute myeloid leukemia caused by MLL-AF9 fusion gene, and that simultaneous inhibition of PRC2-EZH1 and PRC2-EZH2 is necessary for this purpose.

[0089] The compound represented by the general formula (I) and intermediates for production thereof can be produced through the use of various reactions known in the art as described below.

[0090] The compound of the present invention or the pharmacologically acceptable salt thereof can be produced by use of various production methods known in the art taking into account the chemical properties of the backbone and its

substituents. The methods known in the art are methods described in, for example, "Organic Functional Group Preparations", 2nd ed., Academic Press, Inc., 1989 and "Comprehensive Organic Transformations", VCH Publishers Inc., 1989.

[0091] Depending on the type of functional group(s) present in the compound, functional group(s) in a starting material or an intermediate may be protected with an appropriate protective group, or may be replaced with a group that can be readily converted to the functional group. [0094] According to such a method, reaction can be carried out after introduction of the group, followed by the removal of the protective group or the conversion to the desired group according to the need to obtain the desired compound.

[0095] A prodrug of the compound can be produced by, as in the case of the protective group mentioned above, introducing a particular group into a starting material or an intermediate, or by carrying out a reaction using the obtained compound. The reaction for producing the prodrug can be carried out by use of a method generally known to those skilled in the art such as conventional esterification, amidation, dehydration, or hydrogenation.

[0096] Hereinafter, methods for producing compounds will be described. However, the production method of the present invention is not limited to the methods described below by any means.

Then, each well was washed with 50 μL of a washing buffer (50 mM Tris (pH 7.6) and 150 mM NaCl) twice. Then, the residual radioactivity was measured using TopCount NXT HTS (PerkinElmer, Inc., model C384V01). On the basis of the measured residual radioactivity, the extent of enzyme inhibition by the compounds of Examples 1 to 77 was measured at each concentration, and the obtained data was analyzed with medical statistical analysis software GraphPad Prism (GraphPad Software, Inc.) to calculate IC₅₀ values. The PRC2-EZH1 complex was purchased from Reaction Biology Corp. (#HMT-25-115). The biotin-H3 peptide was prepared by the synthesis of a sequence from the 12- to 40-positions of human histone H3 protein (GGKAPRKQLATKAARKSAPATGGVKKPHR), followed by N-terminal biotinylation.

Intracellular H3K27me3 inhibitory activity evaluation

[0492] HCT116 cells were inoculated at 1500 cells/90 μL/well to a 96-well plate (IWAKI, #3860-096) and cultured overnight at 37°C. The HCT116 cells were purchased from American Type Culture Collection (ATCC). Then, 10 μL each of solutions containing the compounds of Examples 1 to 77 was added to each well, and the cells were cultured at 37°C for 3 days. Intracellular H3K27me3 was quantified using AlphaLISA H3K27me3 Cellular Detection Kit (PerkinElmer, Inc., #AL722F). The cells thus cultured in each well were washed with 100 μL of PBS. Cell-Histone Lysis buffer diluted 6-fold with PBS was added thereto at 80 μL/well, and the plate was then incubated at room temperature for 15 minutes while shaken. Then, Cell-Histone Extraction buffer was added thereto at 40 μL/well, and the plate was incubated at room temperature for 10 minutes while shaken. 10 μL of the reaction solution was transferred from each well to each well of a 384-well plate (PerkinElmer, Inc., #6008350). An AlphaLISA anti-H3K27me3 Acceptor beads/Biotinylated Antibody anti-Histone H3 (C-ter) mixed solution was added thereto at 3.3 μL/well, and the plate was incubated at room temperature for 60 minutes. Then, Streptavidin (SA)-coated Donor beads were added thereto at 3.3 μL/well, and the plate was incubated at room temperature for 30 minutes with the plate shielded from light. Signals were measured using EnVision 2104 Multilabel Reader (PerkinElmer, Inc.). The extent of H3K27me3 inhibition by the compounds of Examples 1 to 77 was measured at each concentration, and the obtained data was analyzed with medical statistical analysis software GraphPad Prism to calculate IC₅₀ values.

[Test Example 4]

Cell growth inhibitory activity evaluation

[0494] Cells were purchased from ATCC (G401 (human kidney-derived rhabdoid tumor), HepG2, LNCaP, LS180, MV4;11, NCI-H1563, NCI-H1703, NCI-H520, NCI-H522, NCI-N87, RS4;11, and THP-1), Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH (DSMZ) (KARPAS-422 (EZH2 Y641N mutant human diffuse large B-cell lymphoma) and KOPN8), and Health Science Research Resource Bank (OVMANA). The media for the culture of each cell line used were an EMEM medium supplemented with 10% FBS (LS180 and HepG2), a McCoy's 5A medium supplemented with 10% FBS (G401 (rhabdoid tumor cell line deficient in SNF5, a subunit of the SWI/SNF complex)), an RPMI1640 medium supplemented with 10% FBS (KOPN8, RS4;11, MV4;11, NCI-H1703, NCI-N87, NCI-H522, THP-1, LNCaP, OVMANA, NCI-H520, and NCI-H1563), and an RPMI1640 medium supplemented with 20% FBS (KARPAS-422). During the test period, DMSO (final concentration: 0.1%) or a solution of the compound of Example 14 in DMSO (final concentration: 1 μM (final concentration of DMSO: 0.1%)) was added to the medium, and the cells of each line were cultured at 37°C under 5% CO₂. The cultured cells of each line were inoculated to a 6-well culture plate for cell culture and subcultured for a total of 10 days to 11 days while passage or medium replacement was carried out at 3-day to 4-day intervals. Then, the cells were inoculated to a 96-well assay plate. On the day of inoculation to the 96-well assay plate (inoculation date) and 4 days or 5 days thereafter (effect determination date), reaction was carried out using CellTiter-Glo Luminescent Cell Viability Assay reagent (Promega Corp., #G7573) or ATPlite 1step Luminescence Assay System (PerkinElmer, Inc., #6016739) according to the attached manual. Then, the luminescence intensity of each well was measured using a plate reader (EnVision, PerkinElmer, Inc.). The extent of cell growth inhibition was calculated from the luminescence intensity of a sample-supplemented group (T_S) and a DMSO-supplemented group (C_S) measured on the inoculation date and a sample-supplemented group (T) and a DMSO-supplemented group (C) measured on the effect determination date according to the following expression:

$$\text{Extent of cell growth inhibition (\%)} = \{1 - (T - T_S) / (C - C_S)\} \times 100$$

[0495] When the number of cells in the sample-supplemented group is decreased on the determination date compared with the inoculation date (T < T_S), a cytotoxic effect was calculated according to the following expression:

$$\text{Cytocidal rate (\%)} = (T - T_s) / T_s \times (-100)$$

[0496] The results are shown in Table 2.

EP 3 121 175 B1

subcutaneously transplanted models in Test Example 5, and the antitumor activity against the human kidney-derived rhabdoid tumor G401-subcutaneously transplanted models in Test Example 6 were calculated on their respective test completion dates according to the following expression:

TVC = (Tumor volume of each individual on the test completion date) - (Tumor volume of each individual on the grouping date)

TVCt: Average TVC of the drug administration group

TVCc: Average TVC of the non-administration group

[0500] As for a group whose extent of tumor growth inhibition exceeded 100% (indicated by > 100%), the extent of tumor regression was calculated according to the following expression:

$$\text{Extent of tumor regression (\%)} = \text{Average value of } (1 - (\text{Tumor volume of each individual on the test completion date} / \text{Tumor volume of each individual on the grouping date}) \times 100$$
